1 About this Manual

1.1 Introduction

The OpenRISC 1000 system architecture manual defines the architecture for a family of open-source, synthesizable RISC microprocessor cores. The OpenRISC 1000 architecture allows for a spectrum of chip and system implementations at a variety of price/performance points for a range of applications. It is a 32/64-bit load and store RISC architecture designed with emphasis on performance, simplicity, low power requirements, and scalability. The OpenRISC 1000 architecture targets medium and high performance networking and embedded computer environments.

This manual covers the instruction set, register set, cache management and coherency, memory model, exception model, addressing modes, operands conventions, and the application binary interface (ABI).

This manual does not specify implementation-specific details such as pipeline depth, cache organization, branch prediction, instruction timing, bus interface etc.

1.2 Authors

If you have contributed to this manual but your name isn't listed here, it is not meant as a slight – We simply don't know about it. Send an email to the maintainer(s), and we'll correct the situation.

Name	E-mail	Contribution
Damjan Lampret	damjanl@opencores.org	Initial document
Chen-Min Chen	jimmy@ee.nctu.edu.tw	Some notes
Marko Mlinar	markom@opencores.org	Fast context switches
Johan Rydberg	jrydberg@opencores.org	ELF section
Matan Ziv-Av	matan@svgalib.org	Several suggestions
Chris Ziomkowski	chris@opencores.org	Several suggestions
Greg McGary	greg@mccgary.org	l.cmov, trap exception
Bob Gardner		Native Speaker Check
Rohit Mathur	rohitmathurs@opencores.org	Technical review and corrections
Maria Bolado	mbolado@teisa.unican.es	Technical review and corrections
ORSoC Yann Vernier	yannv@opencores.org	Technical review and corrections
Julius Baxter	julius@opencores.org	Architecture revision information

Table 1-1. Authors of this Manual

1.3 Document Revision History

The revision history of this manual is presented in the table below.

Revision Date	By	Modifications	Arch. Ver (Maj.Min) – Doc Rev
15/Mar/2000	Damjan Lampret	Initial document	0.0-0
7/Apr/2001	Damjan Lampret	First public release	0.0-1
22/Apr/2001	Damjan Lampret	Incorporated changes from Johan and Matan	0.0-2
16/May/2001	Damjan Lampret	Changed SR, Debug, Exceptions, TT, PM. Added l.cmov, l.ff1, etc.	0.0-3
23/May/2001	Damjan Lampret	Added SR[SUMRA], configuration register etc.	0.0-4
24/May/2001	Damjan Lampret	Changed virtually almost all chapters in some way – major change is addition of configuration registers.	0.0-5
28/May/2001	Damjan Lampret	Changed addresses of some SPRs, removed group SPR group 11, added DCR[CT]=7.	0.0-6
24/Jan/2002	Marko Mlinar	Major check and update	0.0-7
9/Apr/2002	Marko Mlinar	PICPR register removed; l.sys convention added; mtspr/mfspr now use bitwise OR instead of sum	0.0-8
28/July/2002	Jeanne Wiegmann	First overall review & layout adjustment	0.0-9
20/Sep/2002	Rohit Mathur	Second overall review	0.0-10
12/Jan/2003	Damjan Lampret	Synchronization with or1ksim and OR1200 RTL. Not all chapters have been checked.	0.0-11
26/Jan/2003	Damjan Lampret	Synchronization with or1ksim and OR1200 RTL. From this revision on the manual carries revision number 1.0 and parts of the architecture that are implemented in OR1200 will no longer change because OR1200 is being implemented in silicon. Major parts that are not implemented in OR1200 and could change in the future include ORFPX, ORVDX, PCU, fast context switching, and 64-bit extension.	0.0-12

Revision Date	By	Modifications	Arch. Ver (Maj.Min) – Doc Rev
26/Jun/2004	Damjan Lampret	Fixed typos in instruction set description reported by Victor Lopez, Giles Hall and Luís Vitório Cargnini. Fixed typos in various chapters reported by Matjaz Breskvar. Changed description of PICSR. Updated ABI chapter based on agreed ABI from the openrisc mailing list. Removed DMR1[ETE], clearly defined watchpoints&breakpoint, split long watchpoint chain into two, removed WP10 and removed DMR1[DXFW], updated DMR2. Fixed FP definition (added FP exception. FPCSR register).	0.0-13
3/Nov/2005	Damjan Lampret	Corrected description of l.ff1, added l.fl1 instruction, corrected encoding of l.maci and added more description of tick timer.	0.0-14
15/Nov/2005	Damjan Lampret	Corrected description of l.sfXXui (arch manual had a wrong description compared to behavior implemented in or1ksim/gcc/or1200). Removed Atomicity chapter.	0.0-15
22/Mar/2011	ORSoC Yann Vernier	Converted to OpenDocument, ABI review, added instruction index and machine code reference table, added ORFPX and ORVDX headings, corrected descriptions for l.div, l.divu, l.ff1, l.fl1, l.mac*, l.mulu, l.msb, l.sub, lv.cmp_*.h, lv.muls.h, lv.pack.h, lv.subus.b, TLBTR, OF64S, specified link register for l.jal and l.jalr, PPN sizes, adjusted instruction classes, various typographical cleanups, clarified delay slot and exception interaction for l.j* and l.sys, removed empty 32-bit implementation for lv.pack/unpack to prevent blank pages	0.0-16
6/Aug/2011	Julius Baxter	Added architecture revision information.	0.0-17

Revision Date	By	Modifications	Arch. Ver (Maj.Min) – Doc Rev
05/Dec/2012	Julius Baxter	<p>Architecture version update</p> <p>Clarify unimplemented SPR space to be read as zero, writing to have no effect</p> <p>Clarify GPR0 implementation and use</p> <p>Remove l.trap instruction's conditional execution function</p> <p>Update ABI statement on returning structures by value</p> <p>Fix typo in register width description of l.sfl.e.d instruction</p> <p>Add UVRP bit in VR</p> <p>Add description of SPR VR2</p> <p>Add description of SPR AVR</p> <p>Add description of SPR EVBAR</p> <p>Mention implication of EVBAR in appropriate sections</p> <p>Add description of ISR SPRs</p> <p>Add presence bits for AVR, EVBAR, ISRs to CPUCFGR</p> <p>Add ND bit to CPUCFGR and mention optional delay slot in appropriate sections</p> <p>Mention exceptions possible for all branch/jump instructions</p> <p>Add description of SPRs AECR, AESR</p> <p>Add presence bits for AECR and AESR to CPUCFGR</p> <p>Clarify overflow exception behavior for appropriate unsigned and signed arithmetic instructions (l.add, l.addi, l.addc, l.addic, l.mul, l.muli, l.mulu, l.div, l.divu, l.sub, l.mac, l.maci, l.msb)</p> <p>Remove "signed" from name of addition and subtraction instructions, as they are used for both unsigned and signed arithmetic</p> <p>Add l.macu and l.msbu instructions for performing unsigned MAC operations</p> <p>Add l.muld and l.muldu for performing multiplication and allowing the 64-bit result to be accessible on 32-bit implementations</p>	1.0-0

Table 1-2. Revision History

1.4 Work in Progress

This document is *work in progress*. Anything in the manual could change until we have made our first silicon. The latest version is always available from OPENCORES revision control (Subversion as of this writing). See details about how to get it on www.opencores.org.

We are currently looking for people to work on and maintain this document. If you would like to contribute, please send an email to one of the authors.

1.5 Fonts in this Manual

In this manual, fonts are used as follows:

- ✓ Typewriter font is used for programming examples.
- ✓ **Bold** font is used for emphasis.
- ✓ UPPER CASE items may be either acronyms or register mode fields that can be written by software. Some common acronyms appear in the glossary.
- ✓ Square brackets [] indicate an addressed field in a register or a numbered register in a register file.

1.6 Conventions

<code>l.mnemonic</code>	Identifies an ORBIS32/64 instruction.
<code>lv.mnemonic</code>	Identifies an ORVDX32/64 instruction.
<code>lf.mnemonic</code>	Identifies an ORFPX32/64 instruction.
<code>0x</code>	Indicates a hexadecimal number.
<code>rA</code>	Instruction syntax used to identify a general purpose register
<code>REG[FIELD]</code>	Syntax used to identify specific bit(s) of a general or special purpose register. FIELD can be a name of one bit or a group of bits or a numerical range constructed from two values separated by a colon.
<code>X</code>	In certain contexts, this indicates a 'don't care'.
<code>N</code>	In certain contexts, this indicates an undefined numerical value.
<code>Implementation</code>	An actual processor implementing the OpenRISC 1000 architecture.
<code>Unit</code>	Sometimes referred to as a coprocessor. An implemented unit usually with some special registers and controlling instructions. It can be defined by the architecture or it may be custom.
<code>Exception</code>	A vectored transfer of control to supervisor software through an exception vector table. A way in which a processor can request operating system assistance (division by zero, TLB miss, external interrupt etc).
<code>Privileged</code>	An instruction (or register) that can only be executed (or accessed) when the processor is in supervisor mode (when <code>SR[SM]=1</code>).

Table 1-3. Conventions

1.7 Numbering

All numbers are decimal or hexadecimal unless otherwise indicated. The prefix `0x` indicates a hexadecimal number. Decimal numbers don't have a special prefix. Binary and other numbers are marked with their base.

2 Architecture Overview

This chapter introduces the OpenRISC 1000 architecture and describes the general architectural features.

2.1 Features

The OpenRISC 1000 architecture includes the following principal features:

- ✓ A completely free and open architecture.
- ✓ A linear, 32-bit or 64-bit logical address space with implementation-specific physical address space.
- ✓ Simple and uniform-length instruction formats featuring different instruction set extensions:
 - OpenRISC Basic Instruction Set (ORBIS32/64) with 32-bit wide instructions aligned on 32-bit boundaries in memory and operating on 32- and 64-bit data
 - OpenRISC Vector/DSP eXtension (ORV DX64) with 32-bit wide instructions aligned on 32-bit boundaries in memory and operating on 8-, 16-, 32- and 64-bit data
 - OpenRISC Floating-Point eXtension (ORFPX32/64) with 32-bit wide instructions aligned on 32-bit boundaries in memory and operating on 32- and 64-bit data
- ✓ Two simple memory addressing modes, whereby memory address is calculated by:
 - addition of a register operand and a signed 16-bit immediate value
 - addition of a register operand and a signed 16-bit immediate value followed by update of the register operand with the calculated effective address
- ✓ Two register operands (or one register and a constant) for most instructions who then place the result in a third register
- ✓ Shadowed or single 32-entry or narrow 16-entry general purpose register file
- ✓ Optional branch delay slot for keeping the pipeline as full as possible
- ✓ Support for separate instruction and data caches/MMUs (Harvard architecture) or for unified instruction and data caches/MMUs (Stanford architecture)
- ✓ A flexible architecture definition that allows certain functions to be performed either in hardware or with the assistance of implementation-specific software
- ✓ Number of different, separated exceptions simplifying exception model
- ✓ Fast context switch support in register set, caches, and MMUs

2.2 Introduction

The OpenRISC 1000 architecture is a completely open architecture. It defines the architecture of a family of open source, RISC microprocessor cores. The OpenRISC 1000 architecture allows for a spectrum of chip and system implementations at a variety of price/performance points for a range of applications. It is a 32/64-bit load and store RISC architecture designed with emphasis on performance, simplicity, low power requirements, and scalability. OpenRISC 1000 targets medium and high performance networking and embedded computer environments.

Performance features include a full 32/64-bit architecture; vector, DSP and floating-point instructions; powerful virtual memory support; cache coherency; optional SMP and SMT support, and support for fast context switching. The architecture defines several features for networking and embedded computer environments. Most notable are several instruction extensions, a configurable number of general-purpose registers, configurable cache and TLB sizes, dynamic power management support, and space for user-provided instructions.

The OpenRISC 1000 architecture is the predecessor of a richer and more powerful next generation of OpenRISC architectures.

The full source for implementations of the OpenRISC 1000 architecture is available at www.opencores.org and is supported with GNU software development tools and a behavioral simulator. Most OpenRISC implementations are designed to be modular and vendor-independent. They can be interfaced with other open-source cores available at www.opencores.org.

Opencores.org encourages third parties to design and market their own implementations of the OpenRISC 1000 architecture and to participate in further development of the architecture.

2.3 Architecture Version Information

It is anticipated that revisions of the OR1K architecture will come about as architectural modifications are made over time. This document shall be valid for the latest version stated in it. Each implementation should indicate the minimum revision it supports in the Architecture Version Register (AVR).

The following table lists the versions and their release date.

Version	Date	Summary
0.0	November 2005	Initial architecture specification.
1.0	December 2012	First version.

Table 2-1: Architecture Version Information

3 Addressing Modes and Operand Conventions

This chapter describes memory-addressing modes and memory operand conventions defined by the OpenRISC 1000 system architecture.

3.1 Memory Addressing Modes

The processor computes an effective address when executing a memory access instruction or branch instruction or when fetching the next sequential instruction. If the sum of the effective address and the operand length exceeds the maximum effective address in logical address space, the memory operand wraps around from the maximum effective address through effective address 0.

3.1.1 Register Indirect with Displacement

Load/store instructions using this address mode contain a signed 16-bit immediate value, which is sign-extended and added to the contents of a general-purpose register specified in the instruction.

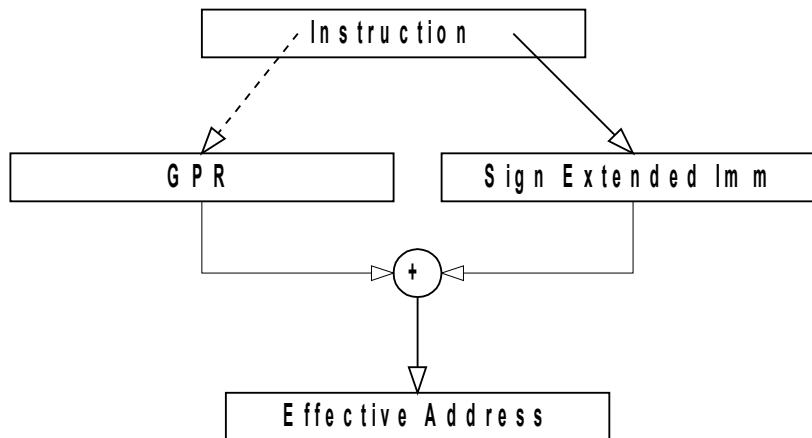

Figure 3-1. Register Indirect with Displacement Addressing

Figure 3-1 shows how an effective address is computed when using register indirect with displacement addressing mode.

3.1.2 PC Relative

Branch instructions using this address mode contain a signed 26-bit immediate value that is sign-extended and added to the contents of a Program Counter register. Before the execution at the destination PC, instruction in delay slot is executed if the ND bit in CPU Configuration Register (CPUCFGR) is set.

Figure 3-2. PC Relative Addressing

Figure 3-2 shows how an effective address is generated when using PC relative addressing mode.

3.2 Memory Operand Conventions

The architecture defines an 8-bit byte, 16-bit halfword, a 32-bit word, and a 64-bit doubleword. It also defines IEEE-754 compliant 32-bit single precision float and 64-bit double precision float storage units. 64-bit vectors of bytes, 64-bit vectors of halfwords, 64-bit vectors of singlewords, and 64-bit vectors of single precision floats are also defined.

Type of Data	Length in Bytes	Length in Bits
Byte	1	8
Halfword (or half)	2	16
Singleword (or word)	4	32
Doubleword (or double)	8	64
Single precision float	4	32
Double precision float	8	64
Vector of bytes	8	64
Vector of halfwords	8	64
Vector of singlewords	8	64

Type of Data	Length in Bytes	Length in Bits
Vector of single precision floats	8	64

Table 3-1. Memory Operands and their sizes

3.2.1 Bit and Byte Ordering

Byte ordering defines how the bytes that make up halfwords, singlewords and doublewords are ordered in memory. To simplify OpenRISC implementations, the architecture implements Most Significant Byte (MSB) ordering – or big endian byte ordering by default. But implementations can support Least Significant Byte (LSB) ordering if they implement byte reordering hardware. Reordering is enabled with bit SR[LEE].

The figures below illustrate the conventions for bit and byte numbering within various width storage units. These conventions hold for both integer and floating-point data, where the most significant byte of a floating-point value holds the sign and at least significant byte holds the start of the exponent.

Table 3-2 shows how bits and bytes are ordered in a halfword.

Bit 15	Bit 8	Bit 7	Bit 0
MSB		LSB	
Byte address 0		Byte address 1	

Table 3-2. Default Bit and Byte Ordering in Halfwords

Table 3-3 shows how bits and bytes are ordered in a singleword.

Bit 31	Bit 24	Bit 23	Bit 16	Bit 15	Bit 8	Bit 7	Bit 0
MSB				LSB			
Byte address 0		Byte address 1		Byte address 2		Byte address 3	

Table 3-3. Default Bit and Byte Ordering in Singlewords and Single Precision Floats

Table 3-4 shows how bits and bytes are ordered in a doubleword.

Bit 63	Bit 56		
MSB			
Byte address 0	Byte address 1	Byte address 2	Byte address 3
			Bit 7
			Bit 0
			LSB
Byte address 4	Byte address 5	Byte address 6	Byte address 7

Table 3-4. Default Bit and Byte Ordering in Doublewords, Double Precision Floats and all Vector Types

3.2.2 Aligned and Misaligned Accesses

A memory operand is naturally aligned if its address is an integral multiple of the operand length. Implementations might support accessing unaligned memory operands, but the default behavior is that accesses to unaligned operands result in an alignment exception. See chapter Exception Model on page 252 for information on alignment exception.

Current OR32 implementations (OR1200) do not implement 8 byte alignment, but do require 4 byte alignment. Therefore the Application Binary Interface (chapter 16) uses 4 byte alignment for 8 byte types. Future extensions such as ORVFX64 may require natural alignment.

Operand	Length	addr[3:0] if aligned
Byte	8 bits	Xxxx
Halfword (or half)	2 bytes	Xxx0
Singleword (or word)	4 bytes	Xx00
Doubleword (or double)	8 bytes	X000
Single precision float	4 bytes	Xx00
Double precision float	8 bytes	X000
Vector of bytes	8 bytes	X000
Vector of halfwords	8 bytes	X000
Vector of singlewords	8 bytes	X000
Vector of single precision floats	8 bytes	X000

Table 3-5. Memory Operand Alignment

OR32 instructions are four bytes long and word-aligned.

4 Register Set

4.1 Features

The OpenRISC 1000 register set includes the following principal features:

- ✓ Thirty-two or sixteen 32/64-bit general-purpose registers – OpenRISC 1000 implementations optimized for use in FPGAs and ASICs in embedded and similar environments may implement only the first sixteen of the possible thirty-two registers.
- ✓ All other registers are special-purpose registers defined for each unit separately and accessible through the `l.mtspr/l.mfspr` instructions.

4.2 Overview

An OpenRISC 1000 processor includes several types of registers: user level general-purpose and special-purpose registers, supervisor level special-purpose registers and unit-dependent registers.

User level general-purpose and special-purpose registers are accessible both in user mode and supervisor mode of operation. Supervisor level special-purpose registers are accessible only in supervisor mode of operation ($SR[SM]=1$).

Unit dependent registers are usually only accessible in supervisor mode but there can be exceptions to this rule. Accessibility for architecture-defined units is defined in this manual. Accessibility for custom units not covered by this manual will be defined in the appropriate implementation-specific manuals.

4.3 Special-Purpose Registers

The special-purpose registers of all units are grouped into thirty-two groups. Each group can have different register address decoding depending on the maximum theoretical number of registers in that particular group. A group can contain registers from several different units or processes. The $SR[SM]$ bit is also used in register address decoding, as some registers are accessible only in supervisor mode. The `l.mtspr` and `l.mfspr` instructions are used for reading and writing registers.

Unimplemented SPRs should read as zero. Writing to unimplemented SPRs will have no effect, and the `l.mtspr` instruction will effectively be a no-operation.

GROUP #	UNIT DESCRIPTION
0	System Control and Status registers
1	Data MMU (in the case of a single unified MMU, groups 1 and 2 decode into a single set of registers)
2	Instruction MMU (in the case of a single unified MMU, groups 1 and 2 decode into a single set of registers)
3	Data Cache (in the case of a single unified cache, groups 3 and 4 decode into a single set of registers)
4	Instruction Cache (in the case of a single unified cache, groups 3 and 4 decode into a single set of registers)
5	MAC unit
6	Debug unit
7	Performance counters unit
8	Power Management
9	Programmable Interrupt Controller
10	Tick Timer
11	Floating Point unit
12-23	Reserved for future use
24-31	Custom units

Table 4-1. Groups of SPRs

An OpenRISC 1000 processor implementation is required to implement at least the special purpose registers from group 0. All other groups are optional, and registers from these groups are implemented only if the implementation has the corresponding unit. Which units are actually implemented may be determined by reading the UPR register from group 0.

A 16-bit SPR address is made of 5-bit group index (bits 15-11) and 11-bit register index (bits 10-0).

Table 4-2. List of All Special-Purpose Registers

SPRs with R* for user mode access are readable in user mode if SR[SUMRA] is set.

The MACLO and MACHI registers are synchronized, such that any ongoing MAC operation finishes before they are read or written.

4.4 General-Purpose Registers (GPRs)

The thirty-two general-purpose registers are labeled R0-R31 and are 32 bits wide in 32-bit implementations and 64 bits wide in 64-bit implementations. They hold scalar integer data, floating-point data, vectors or memory pointers. Table 4-3 contains a list of general-purpose registers. The GPRs may be accessed as both source and destination registers by ORBIS, ORVDX and ORFPX instructions.

See chapter Application Binary Interface on page 329 for information on floating-point data types. See also Register Usage on page 332, where r9 is defined as the Link Register.

Register					r31	r30
Register	r29	r28	r27	r26	r25	r24
Register	r23	r22	r21	r20	r19	r18
Register	r17	r16	r15	r14	r13	r12
Register	r11	r10	r9 LR	r8	r7	r6
Register	r5	r4	r3	r2	r1	r0

Table 4-3. General-Purpose Registers

R0 should always hold a zero value. It is the responsibility of software to initialize it. (This differs from architecture version 0 which commented on implementation and that it should never be used as a destination register – this is no longer specified.) Functions of other registers are explained in chapter Application Binary Interface on page 329.

An implementation may have several sets of GPRs and use them as shadow registers, switching between them whenever a new exception occurs. The current set is identified by the SR[CID] value.

An implementation is not required to initialize GPRs to zero during the reset procedure. The reset exception handler is responsible for initializing GPRs to zero if that is necessary.

4.5 Support for Custom Number of GPRs

Programs may be compiled with less than thirty-two registers. Unused registers are disabled (set as *fixed* registers) when compiling code. Such code is also executable on normal implementations with thirty-two registers but not vice versa. This feature is quite useful since users are expected to move from less powerful OpenRISC implementations with less than thirty-two registers to more powerful thirty-two register OpenRISC implementations.

If configuration registers are implemented, CPUCFGR[CGF] indicates whether implementation has complete thirty-two general-purpose registers or less than thirty-two registers. OR1200 has been implemented with 16 or 32 registers.

4.6 Supervision Register (SR)

The Supervision register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode only.

The SR value defines the state of the processor.

Table 4-4. SR Field Descriptions

4.7 Exception Program Counter Registers (EPCR0 - EPCR15)

The Exception Program Counter registers are special-purpose supervisor-level registers accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode. Read access in user mode is possible if it is enabled in `PCMRx[SUMRA]`. They are 32-bit wide registers in 32-bit implementations and can be wider than 32 bits in 64-bit implementations.

After an exception, the EPCR is set to the program counter address (PC) of the instruction that was interrupted by the exception. If only one EPCR is present in the

implementation (Fast Context Switching (Optional) disabled), it must be saved by the exception handler routine before exception recognition is re-enabled in the SR.

EPC	Exception Program Counter Address
-----	-----------------------------------

Table 4-5. EPCR Field Descriptions

4.8 Exception Effective Address Registers (EEAR0-EEAR15)

The Exception Effective Address registers are special-purpose supervisor-level registers accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode. Read access in user mode is possible if it is enabled in `SR[SUMRA]`. The EEARs are 32-bit wide registers in 32-bit implementations and can be wider than 32 bits in 64-bit implementations.

After an exception, the EEAR is set to the effective address (EA) generated by the faulting instruction. If only one EEAR is present in the implementation, it must be saved by the exception handler routine before exception recognition is re-enabled in the SR.

4.9 Exception Supervision Registers (ESR0-ESR15)

The Exception Supervision registers are special-purpose supervisor-level registers accessible with `l.mtspr/l.mfspr` instructions in supervisor mode. They are 32 bits wide registers in 32-bit implementations and can be wider than 32 bits in 64-bit implementations.

After an exception, the Supervision register (SR) is copied into the ESR. If only one ESR is present in the implementation, it must be saved by the exception handler routine before exception recognition is re-enabled in the SR.

Table 4-7. ESR Field Descriptions

4.10 Next and Previous Program Counter (NPC and PPC)

The Program Counter registers represent the address just executed and the address instruction just to be executed.

These and the GPR registers mapped into SPR space should only be used for debugging purposes by an external debugger. Applications should use the `l.jal` instruction to obtain the current program counter and arithmetic instructions to obtain GPR register values.

4.11 Floating Point Control Status Register (FPCSR)

Floating point control status register is a 32-bit special-purpose register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode and as read-only register in user mode if enabled in `SR[SUMRA]`.

The FPCSR value controls floating point rounding modes, optional generation of floating point exception and provides floating point status flags. Status flags are updated after every floating point instruction is completed and can serve to determine what caused the floating point exception.

If floating point exception is enabled then FPCSR status flags have to be cleared in floating point exception handler. Status flags are cleared by writing 0 to all status bits.

5 Instruction Set

This chapter describes the OpenRISC 1000 instruction set.

5.1 Features

The OpenRISC 1000 instruction set includes the following principal features:

- ✓ Simple and uniform-length instruction formats featuring five Instruction Subsets
- ✓ OpenRISC Basic Instruction Set (ORBIS32/64) with 32-bit wide instructions aligned on 32-bit boundaries in memory and operating on 32-bit and 64-bit data
- ✓ OpenRISC Vector/DSP eXtension (ORVDX64) with 32-bit wide instructions aligned on 32-bit boundaries in memory and operating on 8-, 16-, 32- and 64-bit data
- ✓ OpenRISC Floating-Point eXtension (ORFPX32/64) with 32-bit wide instructions aligned on 32-bit boundaries in memory and operating on 32-bit and 64-bit data
- ✓ Reserved opcodes for custom instructions

Note: Instructions are divided into instruction classes. Only the basic classes are required to be implemented in an OpenRISC 1000 implementation.

Figure 5-1. Instruction Set

5.2 Overview

OpenRISC 1000 instructions belong to one of the following instruction subsets:

- ✓ ORBIS32:
 - 32-bit integer instructions
 - Basic DSP instructions
 - 32-bit load and store instructions

- Program flow instructions
- Special instructions
- ✓ ORBIS64:
 - 64-bit integer instructions
 - 64-bit load and store instructions
- ✓ ORFPX32:
 - Single-precision floating-point instructions
- ✓ ORFPX64:
 - Double-precision floating-point instructions
 - 64-bit load and store instructions
- ✓ ORVDX64:
 - Vector instructions
 - DSP instructions

Instructions in each subset are also split into two instruction classes according to implementation importance:

- ✓ Class I
- ✓ Class II

Class	Description
I	Instructions in class I must always be implemented.
II	Instructions from class II are optional and an implementation may choose to use some or all instructions from this class based on requirements of the target application.

Table 5-1. OpenRISC 1000 Instruction Classes

l.add**Add****l.add****5.3 ORBIS32/64****Format:**

```
l.add rD, rA, rB
```

Description:

The contents of general-purpose register rA are added to the contents of general-purpose register rB to form the result. The result is placed into general-purpose register rD.

The instruction will set the carry flag on unsigned overflow, and the overflow flag on signed overflow.

32-bit Implementation:

```
rD[31:0] ← rA[31:0] + rB[31:0]
SR[CY]   ← carry (unsigned overflow)
SR[OV]   ← signed overflow
```

64-bit Implementation:

```
rD[63:0] ← rA[63:0] + rB[63:0]
SR[CY]   ← carry (unsigned overflow)
SR[OV]   ← signed overflow
```

Exceptions:

Range Exception on overflow if SR[OVE] and AECR[OVADDE] are set.

Range Exception on carry if SR[OVE] and AECR[CYADDE] are set.

Instruction Class
ORBIS32 I

l.addc**Add and Carry****l.addc****Format:**

```
l.addc rD, rA, rB
```

Description:

The contents of general-purpose register rA are added to the contents of general-purpose register rB and carry SR[CY] to form the result. The result is placed into general-purpose register rD.

The instruction will set the carry flag on unsigned overflow, and the overflow flag on signed overflow.

32-bit Implementation:

```
rD[31:0] ← rA[31:0] + rB[31:0] + SR[CY]
SR[CY]   ← carry (unsigned overflow)
SR[OV]   ← signed overflow
```

64-bit Implementation:

```
rD[63:0] ← rA[63:0] + rB[63:0] + SR[CY]
SR[CY]   ← carry (unsigned overflow)
SR[OV]   ← overflow
```

Exceptions:

Range Exception on overflow if SR[OVE] and AECR[OVADDE] are set.

Range Exception on carry if SR[OVE] and AECR[CYADDE] are set.

Instruction Class
ORBIS32 I

l.and**And****l.and****Format:**

```
l.and rD, rA, rB
```

Description:

The contents of general-purpose register rA are combined with the contents of general-purpose register rB in a bit-wise logical AND operation. The result is placed into general-purpose register rD.

32-bit Implementation:

$$rD[31:0] \leftarrow rA[31:0] \text{ AND } rB[31:0]$$
64-bit Implementation:

$$rD[63:0] \leftarrow rA[63:0] \text{ AND } rB[63:0]$$
Exceptions:

None

Instruction Class
ORBIS32 I

l.cmov**Conditional Move****l.cmov**

31	26	25	21	20	16	15	11	10			9					8	7	4	3	.	.			0
opcode 0x38						D					A					B					reserved					opcode 0x0				reserved				opcode 0xe										
6 bits						5 bits					5 bits					5 bits					1 bit					2 bits				4 bits				4 bits										

Format:

```
l.cmov rD, rA, rB
```

Description:

If SR[F] is set, general-purpose register rA is placed in general-purpose register rD. If SR[F] is cleared, general-purpose register rB is placed in general-purpose register rD.

32-bit Implementation:

$$rD[31:0] \leftarrow SR[F] ? rA[31:0] : rB[31:0]$$
64-bit Implementation:

$$rD[63:0] \leftarrow SR[F] ? rA[63:0] : rB[63:0]$$

Reserved for ORBIS32/64 Custom Instructions

l.cust5 **l.cust5**

31	26	25	.	.	.	21	20	.	.	.	16	15	.	.	.	11	10	5	4	0
opcode 0x3c					D					A					B					L					K							
6 bits					5 bits					5 bits					5 bits					6 bits					5 bits							

Format:

`l.cust5 rD, rA, rB, L, K`

Description:

This fake instruction only allocates instruction set space for custom instructions. Custom instructions are those that are not defined by the architecture but rather by the implementation itself.

32-bit Implementation:

N/A

64-bit Implementation:

N/A

Exceptions:

N/A

l.div**Divide Signed****l.div****Format:**

```
l.div rD, rA, rB
```

Description:

The content of general-purpose register rA are divided by the content of general-purpose register rB, and the result is placed into general-purpose register rD. Both operands are treated as signed integers.

On divide-by zero, rD will be undefined, and the overflow flag will be set. Note that prior revisions of the manual (pre-2011) stored the divide by zero flag in SR[CY].

32-bit Implementation:

```
rD[31:0] ← rA[31:0] / rB[31:0]
SR[OV]   ← rB[31:0] == 0
```

64-bit Implementation:

```
rD[63:0] ← rA[63:0] / rB[63:0]
SR[OV]   ← rB[63:0] == 0
```

Exceptions:

Range Exception when divisor is zero if SR[OVE] and AECR[DBZE] are set.

l.divu**Divide Unsigned****l.divu****Format:**

```
l.divu rD, rA, rB
```

Description:

The content of general-purpose register rA are divided by the content of general-purpose register rB, and the result is placed into general-purpose register rD. Both operands are treated as unsigned integers.

On divide-by zero, rD will be undefined, and the overflow flag will be set.

32-bit Implementation:

$$rD[31:0] \leftarrow rA[31:0] / rB[31:0]$$

$$SR[CY] \leftarrow rB[31:0] == 0$$
64-bit Implementation:

$$rD[63:0] \leftarrow rA[63:0] / rB[63:0]$$

$$SR[CY] \leftarrow rB[63:0] == 0$$
Exceptions:

Range Exception when divisor is zero if `SR[OVE]` and `AECR[DBZE]` are set.

l.extbs**Extend Byte with Sign****l.extbs****Format:**

```
l.extbs rD, rA
```

Description:

Bit 7 of general-purpose register rA is placed in high-order bits of general-purpose register rD. The low-order eight bits of general-purpose register rA are copied into the low-order eight bits of general-purpose register rD.

32-bit Implementation:

```
rD[31:8] ← rA[7]
rD[7:0]  ← rA[7:0]
```

64-bit Implementation:

```
rD[63:8] ← rA[7]
rD[7:0]  ← rA[7:0]
```

Exceptions:

None

l.extbz**Extend Byte with Zero****l.extbz****Format:**

```
l.extbz rD, rA
```

Description:

Zero is placed in high-order bits of general-purpose register rD. The low-order eight bits of general-purpose register rA are copied into the low-order eight bits of general-purpose register rD.

32-bit Implementation:

```
rD[31:8] ← 0
rD[7:0] ← rA[7:0]
```

64-bit Implementation:

```
rD[63:8] ← 0
rD[7:0] ← rA[7:0]
```

Exceptions:

None

l.exths Extend Half Word with Sign l.exths

Format:

```
l.exths rD, rA
```

Description:

Bit 15 of general-purpose register rA is placed in high-order bits of general-purpose register rD. The low-order 16 bits of general-purpose register rA are copied into the low-order 16 bits of general-purpose register rD.

32-bit Implementation:

```
rD[31:16] ← rA[15]
rD[15:0]  ← rA[15:0]
```

64-bit Implementation:

```
rD[63:16] ← rA[15]
rD[15:0]  ← rA[15:0]
```

Exceptions:

None

l.exthz Extend Half Word with Zero l.exthz

Format:

```
l.exthz rD, rA
```

Description:

Zero is placed in high-order bits of general-purpose register rD. The low-order 16 bits of general-purpose register rA are copied into the low-order 16 bits of general-purpose register rD.

32-bit Implementation:

```
rD[31:16] ← 0
rD[15:0]  ← rA[15:0]
```

64-bit Implementation:

```
rD[63:16] ← 0
rD[15:0]  ← rA[15:0]
```

Exceptions:

None

l.extws Extend Word with Sign l.extws

Format:

```
l.extws rD, rA
```

Description:

Bit 31 of general-purpose register rA is placed in high-order bits of general-purpose register rD. The low-order 32 bits of general-purpose register rA are copied from low-order 32 bits of general-purpose register rD.

32-bit Implementation:

$$rD[31:0] \leftarrow rA[31:0]$$

64-bit Implementation:

$$rD[63:32] \leftarrow rA[31]$$

$$rD[31:0] \leftarrow rA[31:0]$$

Exceptions:

None

l.extwz Extend Word with Zero l.extwz

Format:

```
l.extwz rD, rA
```

Description:

Zero is placed in high-order bits of general-purpose register rD. The low-order 32 bits of general-purpose register rA are copied into the low-order 32 bits of general-purpose register rD.

32-bit Implementation:

$$rD[31:0] \leftarrow rA[31:0]$$

64-bit Implementation:

$$rD[63:32] \leftarrow 0$$

$$rD[31:0] \leftarrow rA[31:0]$$

Exceptions:

None

l.ff1**Find First 1****l.ff1**

31	26	25	21	20	16	15	11	10			9					8	7	4	3	0
opcode 0x38				D				A				reserved				reserved		opcode 0x0		reserved				opcode 0xf																				
6 bits				5 bits				5 bits				5 bits				1 bit		2 bits		4 bits				4 bits																				

Format:

```
l.ff1 rD, rA, rB
```

Description:

Position of the lowest order '1' bit is written into general-purpose register rD. Checking for bit '1' starts with bit 0 (LSB), and counting is incremented for every zero bit. If first '1' bit is discovered in LSB, one is written into rD, if first '1' bit is discovered in MSB, 32 (64) is written into rD. If there is no '1' bit, zero is written in rD.

32-bit Implementation:

$$rD[31:0] \leftarrow rA[0] ? 1 : rA[1] ? 2 \dots rA[31] ? 32 : 0$$
64-bit Implementation:

$$rD[63:0] \leftarrow rA[0] ? 1 : rA[1] ? 2 \dots rA[63] ? 64 : 0$$
Exceptions:

None

l.fl1**Find Last 1****l.fl1****Format:**

l.fl1 rD, rA, rB

Description:

Position of the highest order '1' bit is written into general-purpose register rD. Checking for bit '1' starts with bit 31/63 (MSB), and counting is decremented for every zero bit until the last '1' bit is found nearing the LSB. If highest order '1' bit is discovered in MSB, 32 (64) is written into rD, if highest order '1' bit is discovered in LSB, one is written into rD. If there is no '1' bit, zero is written in rD.

32-bit Implementation:

$rD[31:0] \leftarrow rA[31] ? 32 : rA[30] ? 31 \dots rA[0] ? 1 : 0$

64-bit Implementation:

$rD[63:0] \leftarrow rA[63] ? 64 : rA[62] ? 63 \dots rA[0] ? 1 : 0$

Exceptions:

None

Instruction Class
ORBIS32 II

l.jalr**Jump and Link Register****l.jalr****Format:**

```
l.jalr rB
```

Description:

The contents of general-purpose register rB is the effective address of the jump. The program unconditionally jumps to EA. If CPUCFGR[ND] is not set, the jump occurs with a delay of one instruction. The address of the instruction after the delay slot is placed in the link register.

It is not allowed to specify link register r9 (see Register Usage on page 332) as rB. This is because an exception in the delay slot (including external interrupts) may cause l.jalr to be reexecuted.

The value of the link register, if read as an operand in the delay slot will be the *new* value, *not* the old value. If the link register is written in the delay slot, the value written will replace the value stored by the l.jalr instruction.

Note that l.sys should not be placed in the delay slot after a jump.

32-bit Implementation:

```
PC ← rB
```

```
LR ← CPUCFGR[ND] ? JumpInsnAddr + 4 : DelayInsnAddr + 4
```

64-bit Implementation:

```
PC ← rB
```

```
LR ← CPUCFGR[ND] ? JumpInsnAddr + 4 : DelayInsnAddr + 4
```

Exceptions:

```
Alignment
```

```
TLB miss
```

```
Page fault
```

```
Bus error
```

Instruction Class

ORBIS32 I

l.jr**Jump Register****l.jr****Format:**

l.jr rB

Description:

The contents of general-purpose register rB is the effective address of the jump. The program unconditionally jumps to EA. If CPUCFGR[ND] is not set, the jump occurs with a delay of one instruction.

Note that l.sys should not be placed in the delay slot after a jump.

32-bit Implementation:

PC ← rB

64-bit Implementation:

PC ← rB

Exceptions:

Alignment
 TLB miss
 Page fault
 Bus error

Instruction Class
 ORBIS32 I

l.mac Multiply and Accumulate Signed l.mac

Format:

```
l.mac rA, rB
```

Description:

The contents of general-purpose register rA and the contents of general-purpose register rB are multiplied, and the 64 bit result is added to the special-purpose registers MACHI and MACLO. All operands are treated as signed integers.

The instruction will set the overflow flag if signed overflow is detecting during the addition stage.

32-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{MACHI}[31:0]\text{MACLO}[31:0] + \text{rA}[31:0] * \text{rB}[31:0]$$

$$\text{SR}[\text{OV}] \leftarrow \text{signed overflow during addition stage}$$

64-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{MACHI}[31:0]\text{MACLO}[31:0] + \text{rA}[63:0] * \text{rB}[63:0]$$

$$\text{SR}[\text{OV}] \leftarrow \text{signed overflow during addition stage}$$

Exceptions:

Range Exception on signed overflow if SR[OVE] and AECR[OVMACADDE] are set.

Instruction Class
ORBIS32 II

l.macu Multiply and Accumulate Unsigned l.macu

Format:

l.macu rA, rB

Description:

The contents of general-purpose register rA and the contents of general-purpose register rB are multiplied, and the 64 bit result is added to the special-purpose registers MACHI and MACLO. All operands are treated as unsigned integers.

The instruction will set the overflow flag if unsigned overflow is detecting during the addition stage.

32-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{MACHI}[31:0]\text{MACLO}[31:0] + \text{rA}[31:0] * \text{rB}[31:0]$$

SR[CY] ← unsigned overflow during addition stage

64-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{MACHI}[31:0]\text{MACLO}[31:0] + \text{rA}[63:0] * \text{rB}[63:0]$$

SR[CY] ← unsigned overflow during addition stage

Exceptions:

Range Exception on unsigned overflow if SR[OVE] and AECR[CYMACADDE] are set.

Instruction Class
ORBIS32 II

l.msb Multiply and Subtract Signed l.msb

Format:

l.msb rA, rB

Description:

The contents of general-purpose register rA and the contents of general-purpose register rB are multiplied, and the 64 bit result is subtracted from the special-purpose registers MACHI and MACLO. Result of the subtraction is placed into MACHI and MACLO registers. All operands are treated as signed integers.

The instruction will set the overflow flag if signed overflow is detecting during the subtraction stage.

32-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{MACHI}[31:0]\text{MACLO}[31:0] - \text{rA}[31:0] * \text{rB}[31:0]$$

SR[OV] ← signed overflow during subtraction stage

64-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{MACHI}[31:0]\text{MACLO}[31:0] - \text{rA}[63:0] * \text{rB}[63:0]$$

SR[OV] ← signed overflow during subtraction stage

Exceptions:

Range Exception on signed overflow if SR[OVE] and AECR[OVMACADDE] are set.

Instruction Class
ORBIS32 II

l.msbu Multiply and Subtract Signed l.msbu

31	26	25	.	.	.	21	20	.	.	.	16	15	.	.	.	11	10	4	3	.	.	0	
opcode 0x31						reserved					A					B					reserved							opcode 0x4			
6 bits						5 bits					5 bits					5 bits					7 bits							4 bits			

Format:

`l.msbu rA, rB`

Description:

The contents of general-purpose register rA and the contents of general-purpose register rB are multiplied, and the 64 bit result is subtracted from the special-purpose registers MACHI and MACLO. Result of the subtraction is placed into MACHI and MACLO registers. All operands are treated as unsigned integers.

The instruction will set the overflow flag if unsigned overflow is detecting during the subtraction stage.

32-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{MACHI}[31:0]\text{MACLO}[31:0] - \text{rA}[31:0] * \text{rB}[31:0]$$

SR[CY] ← unsigned overflow during subtraction stage

64-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{MACHI}[31:0]\text{MACLO}[31:0] - \text{rA}[63:0] * \text{rB}[63:0]$$

SR[CY] ← unsigned overflow during subtraction stage

Exceptions:

Range Exception on signed overflow if SR[OVE] and AECR[CYMACADDE] are set.

Instruction Class
ORBIS32 II

l.mul**Multiply Signed****l.mul****Format:**

```
l.mul rD, rA, rB
```

Description:

The contents of general-purpose register rA and the contents of general-purpose register rB are multiplied, and the result is truncated to destination register width and placed into general-purpose register rD. Both operands are treated as signed integers.

The instruction will set the overflow flag on signed overflow.

32-bit Implementation:

```
rD[31:0] ← rA[31:0] * rB[31:0]
SR[OV]   ← signed overflow
```

64-bit Implementation:

```
rD[63:0] ← rA[63:0] * rB[63:0]
SR[OV]   ← signed overflow
```

Exceptions:

Range Exception on signed overflow if SR[OVE] and AECR[OVMLE] are set.

l.muld Multiply Signed to Double l.muld

Format:

```
l.muld rA, rB
```

Description:

The contents of general-purpose register rA and the contents of general-purpose register rB are multiplied, and the result is stored in the MACHI and MACLO registers. Both operands are treated as signed integers.

The instruction will set the overflow flag on signed overflow.

32-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{rA}[31:0] * \text{rB}[31:0]$$

64-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{rA}[63:0] * \text{rB}[63:0]$$

$$\text{SR}[\text{OV}] \leftarrow \text{signed overflow}$$

Exceptions:

Range Exception on signed overflow if SR[OVE] and AECR[OVMLE] are set.

l.muldu Multiply Unsigned to Double l.muldu

31	.	.	.	26	25	.	.	.	21	20	.	.	.	16	15	.	.	.	11	10		9			8	7	.	.	.	4	3	.	.		0

6 bits						5 bits					5 bits					5 bits					1 bit	2 bits		4 bits				4 bits							

Format:

```
l.muldu rA, rB
```

Description:

The contents of general-purpose register rA and the contents of general-purpose register rB are multiplied, and the result is stored in the MACHI and MACLO registers. Both operands are treated as unsigned integers.

The instruction will set the overflow flag on unsigned overflow.

32-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{rA}[31:0] * \text{rB}[31:0]$$

64-bit Implementation:

$$\text{MACHI}[31:0]\text{MACLO}[31:0] \leftarrow \text{rA}[63:0] * \text{rB}[63:0]$$

$$\text{SR}[\text{CY}] \leftarrow \text{unsigned overflow}$$

Exceptions:

Range Exception on signed overflow if SR[OVE] and AECR[CYMULE] are set.

l.mulu**Multiply Unsigned****l.mulu****Format:**

```
l.mulu rD, rA, rB
```

Description:

The contents of general-purpose register rA and the contents of general-purpose register rB are multiplied, and the result is truncated to destination register width and placed into general-purpose register rD. Both operands are treated as unsigned integers.

The instruction will set the carry flag on unsigned overflow.

32-bit Implementation:

```
rD[31:0] ← rA[31:0] * rB[31:0]
SR[CY] ← carry (unsigned overflow)
```

64-bit Implementation:

```
rD[63:0] ← rA[63:0] * rB[63:0]
SR[CY] ← carry (unsigned overflow)
```

Exceptions:

Range Exception on unsigned overflow if SR[OVE] and AECR[CYMULE] are set.

l.or**Or****l.or****Format:**

```
l.or rD, rA, rB
```

Description:

The contents of general-purpose register rA are combined with the contents of general-purpose register rB in a bit-wise logical OR operation. The result is placed into general-purpose register rD.

32-bit Implementation:

$$rD[31:0] \leftarrow rA[31:0] \text{ OR } rB[31:0]$$
64-bit Implementation:

$$rD[63:0] \leftarrow rA[63:0] \text{ OR } rB[63:0]$$
Exceptions:

None

Instruction Class
ORBIS32 I

l.ror**Rotate Right****l.ror****Format:**

```
l.ror rD, rA, rB
```

Description:

General-purpose register rB specifies the number of bit positions; the contents of general-purpose register rA are rotated right. The result is written into general-purpose register rD.

32-bit Implementation:

$$rD[31-rB[4:0]:0] \leftarrow rA[31:rB[4:0]]$$

$$rD[31:32-rB[4:0]] \leftarrow rA[rB[4:0]-1:0]$$
64-bit Implementation:

$$rD[63-rB[5:0]:0] \leftarrow rA[63:rB[5:0]]$$

$$rD[63:64-rB[5:0]] \leftarrow rA[rB[5:0]-1:0]$$
Exceptions:

None

Instruction Class
ORBIS32 II

l.rori Rotate Right with Immediate l.rori

Format:

```
l.rori rD, rA, L
```

Description:

The 6-bit immediate value specifies the number of bit positions; the contents of general-purpose register rA are rotated right. The result is written into general-purpose register rD. In 32-bit implementations bit 5 of immediate is ignored.

32-bit Implementation:

```
rD[31-L:0] ← rA[31:L]
rD[31:32-L] ← rA[L-1:0]
```

64-bit Implementation:

```
rD[63-L:0] ← rA[63:L]
rD[63:64-L] ← rA[L-1:0]
```

Exceptions:

None

l.sfeq**Set Flag if Equal****l.sfeq****Format:**

```
l.sfeq rA, rB
```

Description:

The contents of general-purpose registers rA and rB are compared. If the contents are equal, the compare flag is set; otherwise the compare flag is cleared.

32-bit Implementation:

$$SR[F] \leftarrow rA[31:0] == rB[31:0]$$
64-bit Implementation:

$$SR[F] \leftarrow rA[63:0] == rB[63:0]$$
Exceptions:

None

l.srai Shift Right Arithmetic with Immediate l.srai

Format:

```
l.srai rD, rA, L
```

Description:

The 6-bit immediate value specifies the number of bit positions; the contents of general-purpose register rA are shifted right, sign-extending the high-order bits. The result is written into general-purpose register rD. In 32-bit implementations bit 5 of immediate is ignored.

32-bit Implementation:

```
rD[31-L:0] ← rA[31:L]
rD[31:32-L] ← rA[31]
```

64-bit Implementation:

```
rD[63-L:0] ← rA[63:L]
rD[63:64-L] ← rA[63]
```

Exceptions:

None

l.srl**Shift Right Logical****l.srl****Format:**

```
l.srl rD, rA, rB
```

Description:

General-purpose register rB specifies the number of bit positions; the contents of general-purpose register rA are shifted right, inserting zeros into the high-order bits. The result is written into general-purpose register rD. In 32-bit implementations bit 5 of rB is ignored.

32-bit Implementation:

```
rD[31-rB[4:0]:0] ← rA[31:rB[4:0]]
rD[31:32-rB[4:0]] ← 0
```

64-bit Implementation:

```
rD[63-rB[5:0]:0] ← rA[63:rB[5:0]]
rD[63:64-rB[5:0]] ← 0
```

Exceptions:

None

Instruction Class
ORBIS32 I

l.srli Shift Right Logical with Immediate l.srli

Format:

```
l.srli rD, rA, L
```

Description:

The 6-bit immediate value specifies the number of bit positions; the contents of general-purpose register rA are shifted right, inserting zeros into the high-order bits. The result is written into general-purpose register rD. In 32-bit implementations bit 5 of immediate is ignored.

32-bit Implementation:

```
rD[31-L:0] ← rA[31:L]
rD[31:32-L] ← 0
```

64-bit Implementation:

```
rD[63-L:0] ← rA[63:L]
rD[63:64-L] ← 0
```

Exceptions:

None

Instruction Class
ORBIS32 I

l.sub**Subtract****l.sub****Format:**

```
l.sub rD, rA, rB
```

Description:

The contents of general-purpose register rB are subtracted from the contents of general-purpose register rA to form the result. The result is placed into general-purpose register rD.

The instruction will set the carry flag on unsigned overflow, and the overflow flag on signed overflow.

32-bit Implementation:

```
rD[31:0] ← rA[31:0] - rB[31:0]
SR[CY]   ← carry (unsigned overflow)
SR[OV]   ← signed overflow
```

64-bit Implementation:

```
rD[63:0] ← rA[63:0] - rB[63:0]
SR[CY]   ← carry (unsigned overflow)
SR[OV]   ← signed overflow
```

Exceptions:

Range Exception on overflow if SR[OVE] and AECR[OVADDE] are set.

Range Exception on carry if SR[OVE] and AECR[CYADDE] are set.

Instruction Class
ORBIS32 I

l.xor**Exclusive Or****l.xor****Format:**

```
l.xor rD, rA, rB
```

Description:

The contents of general-purpose register rA are combined with the contents of general-purpose register rB in a bit-wise logical XOR operation. The result is placed into general-purpose register rD.

32-bit Implementation:

$$rD[31:0] \leftarrow rA[31:0] \text{ XOR } rB[31:0]$$
64-bit Implementation:

$$rD[63:0] \leftarrow rA[63:0] \text{ XOR } rB[63:0]$$
Exceptions:

31	26	25	.	.	.	21	20	.	.	.	16	15	.	.	.	11	10	.	.	8	7	0
opcode 0x32						D					A					B					reserved			opcode 0x11								
6 bits						5 bits					5 bits					5 bits					3 bits			8 bits								

Format:

`lf.sub.d rD, rA, rB`

Description:

The contents of general-purpose register `rB` are subtracted from the contents of general-purpose register `rA` to form the result. The result is placed into general-purpose register `rD`.

32-bit Implementation:

N/A

64-bit Implementation:

$rD[63:0] \leftarrow rA[63:0] - rB[63:0]$

Exceptions:

Floating Point

opcode 0xa						D					A					B					reserved			opcode 0x1a														
6 bits						5 bits					5 bits					5 bits					3 bits			8 bits														

Format:

```
lv.all_ne.b rD, rA, rB
```

Description:

All byte elements of general-purpose register rA are compared to the byte elements of general-purpose register rB. The compare flag is set if all corresponding elements are not equal; otherwise the compare flag is cleared. The compare flag is replicated into all bit positions of general-purpose register rD.

32-bit Implementation:

N/A

64-bit Implementation:

```
flag      ← rA[7:0]   != rB[7:0]  &&
           rA[15:8]  != rB[15:8]  &&
           rA[23:16] != rB[23:16] &&
           rA[31:24] != rB[31:24] &&
           rA[39:32] != rB[39:32] &&

Multiply Add Signed Saturated

31	26	25	.	.	.	21	20	.	.	.	16	15	.	.	.	11	10	.	.	8	7	0
opcode 0xa				D				A				B				reserved			opcode 0x54													
6 bits				5 bits				5 bits				5 bits				3 bits			8 bits													

Format:

lv.madds.h rD, rA, rB

Description:

The signed half-word elements of general-purpose register rA are multiplied by the signed half-word elements of general-purpose register rB to form intermediate results. They are then added to the signed half-word VMAC elements to form the final results that are placed again in the VMAC registers. The intermediate result is placed into general-purpose register rD. If any of the final results exceeds the min/max value, it is saturated.

Note: The ORVDX instruction set is not completely specified. This instruction is incorrectly specified in that VMAC is not defined and implementation below does not match description.

Vector Half-Word Elements

lv.msubs.h Multiply Subtract Signed Saturated

Format:

lv.msubs.h rD, rA, rB

Description:

The signed half-word elements of general-purpose register rA are multiplied by the signed half-word elements of general-purpose register rB to form intermediate results. They are then subtracted from the signed half-word VMAC elements to form the final results that are placed again in the VMAC registers. The intermediate result is placed into general-purpose register rD. If any of the final results exceeds the min/max value, it is saturated.

Note: The ORVDX instruction set is not completely specified. This instruction is incorrectly specified in that VMAC is not defined and implementation below does not match description.

32-bit Implementation:

N/A

64-bit Implementation:

$$\begin{aligned}
 rD[15:0] &\leftarrow \text{sat32s}(VMACLO[31:0] - rA[15:0] * rB[15:0]) \\
 rD[31:16] &\leftarrow \text{sat32s}(VMACLO[63:32] - rA[31:16] * rB[31:16]) \\
 rD[47:32] &\leftarrow \text{sat32s}(VMACHI[31:0] - rA[47:32] * rB[47:32]) \\
 rD[63:48] &\leftarrow \text{sat32s}(VMACHI[63:32] - rA[63:48] * rB[63:48])
 \end{aligned}$$

6 Exception Model

This chapter describes the various exception types and their handling.

6.1 Introduction

The exception mechanism allows the processor to change to supervisor state as a result of external signals, errors, or unusual conditions arising in the execution of instructions. When exceptions occur, information about the state of the processor is saved to certain registers and the processor begins execution at the address predetermined for each exception. Processing of exceptions begins in supervisor mode.

The OpenRISC 1000 architecture has special support for fast exception processing – also called fast context switch support. This allows very rapid interrupt processing. It is achieved with shadowing general-purpose and some special registers.

The architecture requires that all exceptions be handled in strict order with respect to the instruction stream. When an instruction-caused exception is recognized, any unexecuted instructions that appear earlier in the instruction stream are required to complete before the exception is taken.

Exceptions can occur while an exception handler routine is executing, and multiple exceptions can become nested. Support for fast exceptions allows fast nesting of exceptions until all shadowed registers are used. If context switching is not implemented, nested exceptions should not occur.

6.2 Exception Classes

All exceptions can be described as precise or imprecise and either synchronous or asynchronous. Synchronous exceptions are caused by instructions and asynchronous exceptions are caused by events external to the processor.

Type	Exception
Asynchronous/nonmaskable	Bus Error, Reset
Asynchronous/maskable	External Interrupt, Tick Timer
Synchronous/precise	Instruction-caused exceptions
Synchronous/imprecise	None

Table 6-1. Exception Classes

Whenever an exception occurs, current PC is saved to current EPCR and new PC is set with the vector address according to Table 6-2.

Exception Type	Vector Offset	Causal Conditions
Reset	0x100	Caused by software or hardware reset.
Bus Error	0x200	The causes are implementation-specific, but typically they are related to bus errors and attempts to access invalid physical address.
Data Page Fault	0x300	No matching PTE found in page tables or page protection violation for load/store operations.
Instruction Page Fault	0x400	No matching PTE found in page tables or page protection violation for instruction fetch.
Tick Timer	0x500	Tick timer interrupt asserted.
Alignment	0x600	Load/store access to naturally not aligned location.
Illegal Instruction	0x700	Illegal instruction in the instruction stream.
External Interrupt	0x800	External interrupt asserted.
D-TLB Miss	0x900	No matching entry in DTLB (DTLB miss).
I-TLB Miss	0xA00	No matching entry in ITLB (ITLB miss).
Range	0xB00	If programmed in the SR, the setting of certain flags, like SR[OV], causes a range exception. On OpenRISC implementations with less than 32 GPRs when accessing unimplemented architectural GPRs. On all implementations if SR[CID] had to go out of range in order to process next exception.
System Call	0xC00	System call initiated by software.
Floating Point	0xD00	Caused by floating point instructions when FPCSR status flags are set by FPU and FPCSR[FPEE] is set
Trap	0xE00	Caused by the l.trap instruction or by debug unit.
Reserved	0xF00 – 0x1400	Reserved for future use.
Reserved	0x1500 – 0x1800	Reserved for implementation-specific exceptions.
Reserved	0x1900 – 0x1F00	Reserved for custom exceptions.

Table 6-2. Exception Types and Causal Conditions

6.3 Exception Processing

Whenever an exception occurs, the current/next PC is saved to the current EPCR. If the CPU implements delay-slot execution (CPUCFGR[ND] is not set) and the PC points to the delay-slot instruction, PC-4 is saved to the current EPCR and SR[DSX] is set. Table 6-3 defines what are current/next PC and effective address.

The SR is saved to the current ESR.

Current EPCR/ESR are identified by SR[CID]. If fast context switching is not implemented then current EPCR/ESR are always EPCR0/ESR0.

In addition, the current EEAR is set with the effective address in question if one of the following exceptions occurs: Bus Error, IMMU page fault, DMMU page fault, Alignment, I-TLB miss, D-TLB miss.

Exception	Priority	EPCR (no delay slot)	EPCR (delay slot)	EEAR
Reset	1	-	-	-
Bus Error	4 (insn) 9 (data)	Address of instruction that caused exception	Address of jump instruction before the instruction that caused exception	Load/store/fetch virtual EA
Data Page Fault	8	Address of instruction that caused exception	Address of jump instruction before the instruction that caused exception	Load/store virtual EA
Instruction Page Fault	3	Address of instruction that caused exception	Address of jump instruction before the instruction that caused exception	Instruction fetch virtual EA
Tick Timer	12	Address of next not executed instruction	Address of just executed jump instruction	-
Alignment	6	Address of instruction that caused exception	Address of jump instruction before the instruction that caused exception	Load/store virtual EA
Illegal Instruction	5	Address of instruction that caused exception	Address of jump instruction before the instruction that caused exception	Instruction fetch virtual EA
External Interrupt	12	Address of next not executed instruction	Address of just executed jump instruction	-
D-TLB Miss	7	Address of instruction that caused exception	Address of jump instruction before the instruction that caused exception	Load/store virtual EA
I-TLB Miss	2	Address of instruction that caused exception	Address of jump instruction before the instruction that caused exception	Instruction fetch virtual EA
Range	10	Address of instruction that caused exception	Address of jump instruction before the instruction that caused exception	-
System Call	7	Address of next not executed instruction	Address of just executed jump instruction	-

Exception	Priority	EPCR (no delay slot)	EPCR (delay slot)	EEAR
Floating Point	11	Address of next not executed instruction	Address of just executed jump instruction	-
Trap	7	Address of instruction that caused exception	Address of jump instruction before the instruction that caused exception	-

Table 6-3. Values of EPCR and EEAR After Exception

If fast context switching is used, SR[CID] is incremented with each new exception so that a new set of shadowed registers is used. If SR[CID] will overflow with the current exception, a range exception is invoked.

However, if SR[CE] is not set, fast context switching is not enabled. In this case all registers that will be modified by exception handler routine must first be saved.

All exceptions set a new SR where both MMUs are disabled (address translation disabled), supervisor mode is turned on, and tick timer exceptions and interrupts are disabled. (SR[DME]=0, SR[IME]=0, SR[SM]=1, SR[IEE]=0 and SR[TEE]=0).

When enough machine state information has been saved by the exception handler, SR[TTE] and SR[IEE] can be re-enabled so that tick timer and external interrupts are not blocked.

When returning from an exception handler with **l.rfe**, SR and PC are restored. If SR[CE] is set, CID will be automatically decremented and the previous machine state will be restored; otherwise, general-purpose registers previously saved by exception handler need to be restored as well.

6.3.1 Particular delay slot issues

Instructions placed in the delay slot will cause EPCR to be set to the address of the jump instruction, not the delay slot or target instruction. Because of this, two categories of instruction should never be placed in the delay slot:

1. Instructions altering the conditions of the jump itself. This is why **l.jr** must not have a delay slot instruction modify the target address register.
2. Instructions consistently causing an exception, such as **l.sys**. Normally **l.sys** returns to continue execution, but if placed in a delay slot it instead causes a repeat of the system call itself.

l.trap is generally used as a software breakpoint, so may not have the same concern.

6.4 Fast Context Switching (Optional)

Fast context switching is a technique that reduces register storing to stack when exceptions occur. Only one type of exception can be handled, so it is up to the software to figure out what caused it. Using software, both interrupt handler invocation and thread

switching can be handled very quickly. The hardware should be capable of switching between contexts in only one cycle.

Context can also be switched during an exception or by using a supervisor register CXR (context register) available only in supervisor mode. CXR is the same for all contexts.

6.4.1 Changing Context in Supervisor Mode

The read/write register CXR consists of two parts: the lower 16 bits represents the current context register set. The upper 16 bits represent the current CID. CCID cannot be accessed in user mode. Writing to CCID causes an immediate context change. Reading from CCID returns the running (current) context ID. The context where CID=0 is also called the main context.

BIT	31-16	15-0
Identifier	CCID	CCRS
Reset	0	0

CCRS has two functions:

- ✓ When an exception occurs, it holds the previous CID.
- ✓ It is used to access other context's registers.

6.4.2 Context Switch Caused by Exception

When an exception occurs and fast context switching is enabled, the CCID is copied to CCRS and then set to zero, thus switching to main context.

Functions of the main context are:

- ✓ Switching between threads
- ✓ Handling exceptions
- ✓ Preparing, loading, saving, and releasing context identifiers to/from the CID table

CXR should be stored in a general-purpose register as soon as possible, to allow further exception nesting.

The following table shows an example how the CID table could be used. Generally, there is no need that free exception contexts are equal.

CID	Function
7	Exception contexts
6	
5	
4	Thread contexts

CID	Function
3	
2	
1	
0	Main context

Four thread contexts are loaded, and software can switch between them freely using main context, running in supervisor mode. When an exception occurs, first need to be determined what caused it and switch to the next free exception context. Since exceptions can be nested, more free contexts may have to be available. Some of the contexts thus need to be stored to memory in order to switch to a new exception.

The algorithm used in the main context to handle context saving/restoring and switching can be kept as simple as possible. It should have enough (of its own) registers to store information such as:

- ✓ Current running CID
- ✓ Next exception
- ✓ Thread cycling info
- ✓ Pointers to context table in memory
- ✓ Copy of CXR

If the number of interrupts is significant, some sort of deferred interrupts calls mechanism can be used. The main context algorithm should store just I/O information passed by the interrupt for further execution and return from main context as soon as possible.

6.4.3 Accessing Other Contexts' Registers

This operation can be done only in supervisor mode. In the basic instruction set we have the `l.mtspr` and `l.mfspr` instructions that are used to access shadowed registers.

7 Memory Model

This chapter describes the OpenRISC 1000 weakly ordered memory model.

7.1 Memory

Memory is byte-addressed with halfword accesses aligned on 2-byte boundaries, singleword accesses aligned on 4-byte boundaries, and doubleword accesses aligned on 8-byte boundaries.

7.2 Memory Access Ordering

The OpenRISC 1000 architecture specifies a weakly ordered memory model for uniprocessor and shared memory multiprocessor systems. This model has the advantage of a higher-performance memory system but places the responsibility for strict access ordering on the programmer.

The order in which the processor performs memory access, the order in which those accesses complete in memory, and the order in which those accesses are viewed by another processor may all be different. Two means of enforcing memory access ordering are provided to allow programs in uniprocessor and multiprocessor system to share memory.

An OpenRISC 1000 processor implementation may also implement a more restrictive, strongly ordered memory model. Programs written for the weakly ordered memory model will automatically work on processors with strongly ordered memory model.

7.2.1 Memory Synchronize Instruction

The **l.msinc** instruction permits the program to control the order in which load and store operations are performed. This synchronization is accomplished by requiring programs to indicate explicitly in the instruction stream, by inserting a memory sync instruction, that synchronization is required. The memory sync instruction ensures that all memory accesses initiated by a program have been performed before the next instruction is executed.

OpenRISC 1000 processor implementations, that implement the strongly-ordered memory model instead of the weakly-ordered one, can execute memory synchronization instruction as a no-operation instruction.

7.2.2 Pages Designated as Weakly-Ordered-Memory

When a memory page is designated as a Weakly-Ordered-Memory (WOM) page, instructions and data can be accessed out-of-order and with prefetching. When a page is designated as not WOM, instruction fetches and load/store operations are performed in-order without any prefetching.

OpenRISC 1000 scalar processor implementations, that implement strongly-ordered memory model instead of the weakly-ordered one and perform load and store operations in-order, are not required to implement the WOM bit in the MMU.

8 Memory Management

This chapter describes the virtual memory and access protection mechanisms for memory management within the OpenRISC 1000 architecture.

Note that this chapter describes the address translation mechanism from the perspective of the programming model. As such, it describes the structure of the page tables, the MMU conditions that cause MMU related exceptions and the MMU registers. The hardware implementation details that are invisible to the OpenRISC 1000 programming model, such as MMU organization and TLB size, are not contained in the architectural definition.

8.1 MMU Features

The OpenRISC 1000 memory management unit includes the following principal features:

- ✓ Support for effective address (EA) of 32 bits and 64 bits
- ✓ Support for implementation specific size of physical address spaces up to 35 address bits (32 GByte)
- ✓ Three different page sizes:
 - Level 0 pages (32 Gbyte; only with 64-bit EA) translated with D/I Area Translation Buffer (ATB)
 - Level 1 pages (16 MByte) translated with D/I Area Translation Buffer (ATB)
 - Level 2 pages (8 Kbyte) translated with D/I Translation Lookaside Buffer (TLB)
- ✓ Address translation using one-, two- or three-level page tables
- ✓ Powerful page based access protection with support for demand-paged virtual memory
- ✓ Support for simultaneous multi-threading (SMT)

8.2 MMU Overview

The primary functions of the MMU in an OpenRISC 1000 processor are to translate effective addresses to physical addresses for memory accesses. In addition, the MMU provides various levels of access protection on a page-by-page basis. Note that this chapter describes the conceptual model of the OpenRISC 1000 MMU and implementations may differ in the specific hardware used to implement this model.

Two general types of accesses generated by OpenRISC 1000 processors require address translation – instruction accesses generated by the instruction fetch unit, and data accesses generated by the load and store unit. Generally, the address translation mechanism is defined in terms of page tables used by OpenRISC 1000 processors to locate the effective to physical address mapping for instruction and data accesses.

The definition of page table data structures provides significant flexibility for the implementation of performance enhancement features in a wide range of processors. Therefore, the performance enhancements used to the page table information on-chip vary from implementation to implementation.

Translation lookaside buffers (TLBs) are commonly implemented in OpenRISC 1000 processors to keep recently-used page address translations on-chip. Although their exact implementation is not specified, the general concepts that are pertinent to the system software are described.

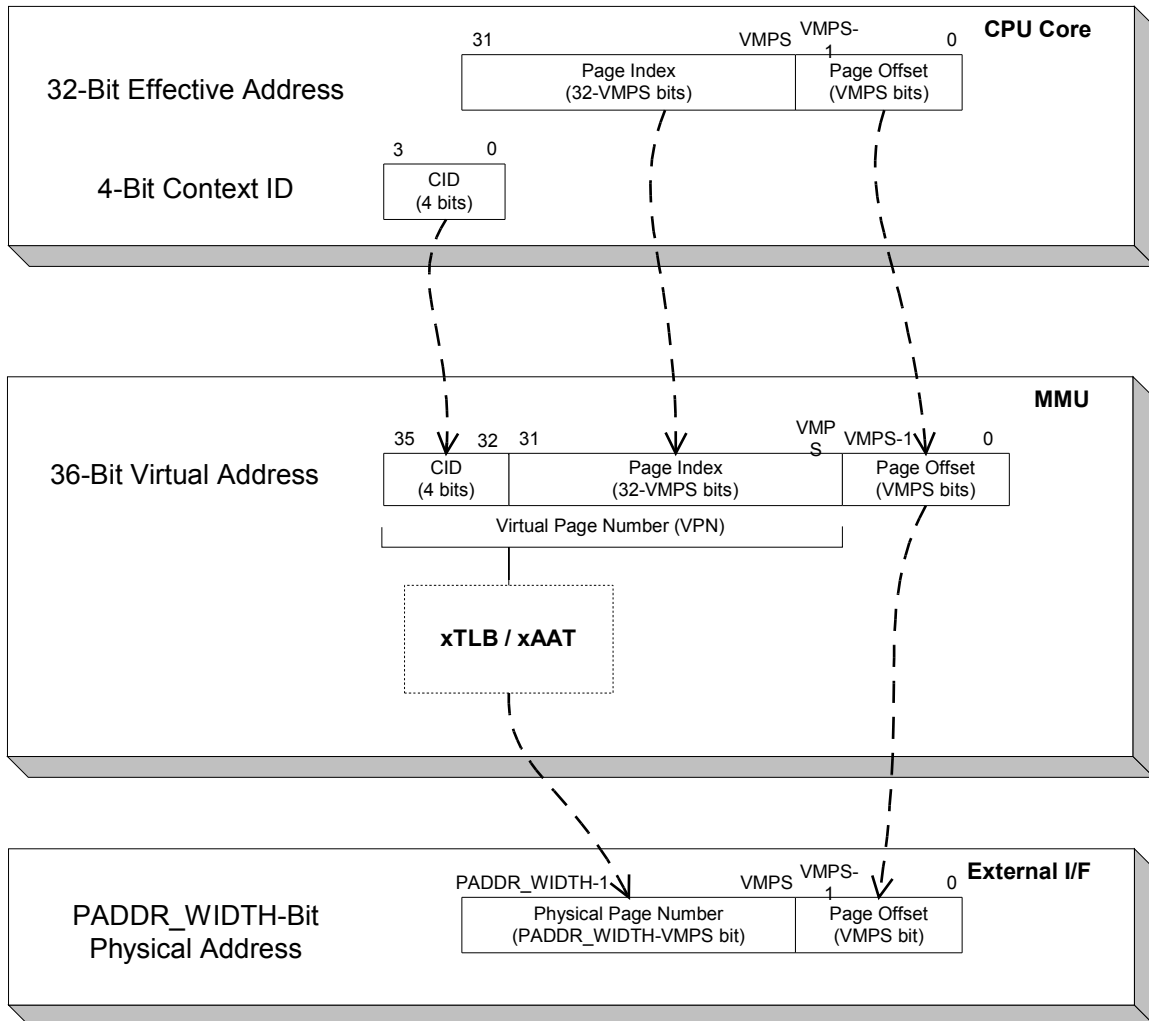

Figure 8-1. Translation of Effective to Physical Address – Simplified block diagram for 32-bit processor implementations

Large areas can be translated with optional facility called Area Translation Buffer (ATB). ATBs translate 16MB and 32GB pages. If xTLB and xATB have a match on the same virtual address, xTLB is used.

The MMU, together with the exception processing mechanism, provides the necessary support for the operating system to implement a paged virtual memory environment and for enforcing protection of designated memory areas.

8.3 MMU Exceptions

To complete any memory access, the effective address must be translated to a physical address. An MMU exception occurs if this translation fails.

TLB miss exceptions can happen only on OpenRISC 1000 processor implementations that do TLB reload in software.

The page fault exceptions that are caused by missing PTE in page table or page access protection can happen on any OpenRISC 1000 processor implementations.

EXCEPTION NAME	VECTOR OFFSET	CAUSING CONDITIONS
Data Page Fault	0x300	No matching PTE found in page tables or page protection violation for load/store operations.
Instruction Page Fault	0x400	No matching PTE found in page tables or page protection violation for instruction fetch.
DTLB Miss	0x900	No matching entry in DTLB.
ITLB Miss	0xA00	No matching entry in ITLB.

Table 8-1. MMU Exceptions

The vector offset addresses in table are subject to the presence and setting of the of the Exception Vector Base Address Register (EVBAR) may have configured the exceptions to be processed at a different offset, however the least-significant 12-bit offset address remain the same.

The state saved by the processor for each of the exceptions in Table 9-2 contains information that identifies the address of the failing instruction. Refer to the chapter entitled “Exception Processing” on page 254 for a more detailed description of exception processing.

8.4 MMU Special-Purpose Registers

Table 8-2 summarizes the registers that the operating system uses to program the MMU. These registers are 32-bit special-purpose supervisor-level registers accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode only.

Table 8-2 does not show two configuration registers that are implemented if implementation implements configuration registers. `DMMUCFGR` and `IMMUCFGR` describe capability of DMMU and IMMU.

Grp #	Reg #	Reg Name	USER MODE	SUPV MODE	Description

Table 8-2. List of MMU Special-Purpose Registers

As TLBs are noncoherent caches of PTEs, software that changes the page tables in any way must perform the appropriate TLB invalidate operations to keep the on-chip TLBs coherent with respect to the page tables in memory.

8.4.1 Data MMU Control Register (DMMUCR)

The DMMUCR is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

It provides general control of the DMMU.

Bit	31-10	9-1	0
Identifier	PTBP	Reserved	DTF
Reset	0	X	0
R/W	R/W	R	R/W

DTF	DTLB Flush 0 DTLB ready for operation 1 DTLB flush request/status
PTBP	Page Table Base Pointer N 22-bit pointer to the base of page directory/table

Table 8-3. DMMUCR Field Descriptions

The PTBP field in the DMMUCR is required only in implementations with hardware PTE reload support. Implementations that use software TLB reload are not required to implement this field because the page table base pointer is stored in a TLB miss exception handler's variable.

The DTF is optional and when implemented it flushes entire DTLB.

8.4.2 Data MMU Protection Register (DMMUPR)

The DMMUPR is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

It defines 7 protection groups indexed by PPI fields in PTEs.

Bit	31-28	27	26	25	24

UREx	User Read Enable x 0 Load operation in user mode not permitted 1 Load operation in user mode permitted
UWEx	User Write Enable x 0 Store operation in user mode not permitted 1 Store operation in user mode permitted

Table 8-4. DMMUPR Field Descriptions

A DMMUPR is required only in implementations with hardware PTE reload support. Implementations that use software TLB reload are not required to implement this

register; instead a TLB miss handler should have a software variable as replacement for the DMMUPR and it should do a software look-up operation and set DTLBW_yTR_x protection bits accordingly.

8.4.3 Instruction MMU Control Register (IMMUCR)

The IMMUCR is a 32-bit special-purpose supervisor-level register accessible with the l.mtspr/l.mfspr instructions in supervisor mode.

It provides general control of the IMMU.

Bit	31-10	9-1	0
Identifier	PTBP	Reserved	ITF
Reset	0	X	0
R/W	R/W	R	R/W

ITF	ITLB Flush 0 ITLB ready for operation 1 ITLB flush request/status
PTBP	Page Table Base Pointer N 22-bit pointer to the base of page directory/table

Table 8-5. IMMUCR Field Descriptions

The PTBP field in xMMUCR is required only in implementations with hardware PTE reload support. Implementations that use software TLB reload are not required to implement this field because the page table base pointer is stored in a TLB miss exception handler's variable.

The ITF is optional and when implemented it flushes entire ITLB.

8.4.4 Instruction MMU Protection Register (IMMUPR)

The IMMUP register is a 32-bit special-purpose supervisor-level register accessible with the l.mtspr/l.mfspr instructions in supervisor mode.

It defines 7 protection groups indexed by PPI fields in PTEs.

Bit	31-14	13	12	11	10	9	8

UXEx	<p>User Execute Enable x</p> <p>0 Instruction fetch in user mode not permitted</p> <p>1 Instruction fetch in user mode permitted</p>

Table 8-6. IMMUPR Field Descriptions

The IMMUPR is required only in implementations with hardware PTE reload support. Implementations that use software TLB reload are not required to implement this register; instead the TLB miss handler should have a software variable as replacement for the IMMUPR register and it should do a software look-up operation and set ITLBWyTRx protection bits accordingly.

8.4.5 Instruction/Data TLB Entry Invalidate Registers (xTLBEIR)

The instruction/data TLB entry invalidate registers are special-purpose registers accessible with the l.mtspr/l.mfspr instructions in supervisor mode. They are 32 bits wide in 32-bit implementations and 64 bits wide in 64-bit implementation.

The xTLBEIR is written with the effective address. The corresponding xTLB entry is invalidated in the local processor.

Bit	31-0
Identifier	EA

Table 8-7. xTLBEIR Field Descriptions

8.4.6 Instruction/Data Translation Lookaside Buffer Way y Match Registers (xTLBWyMR0-xTLBWyMR127)

The xTLBWyMR registers are 32-bit special-purpose supervisor-level registers accessible with the l.mtspr/l.mfspr instructions in supervisor mode.

Together with the xTLBWyTR registers they cache translation entries used for translating virtual to physical address. A virtual address is formed from the EA generated during instruction fetch or load/store operation, and the SR[CID] field. xTLBWyMR registers hold a tag that is compared with the current virtual address generated by the CPU core. Together with the xTLBWyTR registers and match logic they form a core part of the xMMU.

8.4.9 Instruction/Data Area Translation Buffer Match Registers (xATBMR0-xATBMR3)

The xATBMR registers are 32-bit special-purpose supervisor-level registers accessible with the l.mtspr/l.mfspr instructions in supervisor mode.

Together with the xATBTR registers they cache translation entries used for translating virtual to physical address of large address space areas. A virtual address is formed from the EA generated during an instruction fetch or load/store operation, and the SR[CID] field. xATBMR registers hold a tag that is compared with the current virtual address generated by the CPU core. Together with the xATBTR registers and match logic they form a core part of the xMMU.

The CID bits can be hardwired to zero if the implementation does not support fast context switching and SR[CID] bits.

8.4.10 Data Area Translation Buffer Translate Registers (DATBTR0-DATBTR3)

The DATBTR registers are 32-bit special-purpose supervisor-level registers accessible with the l.mtspr/l.mfspr instructions in supervisor mode.

Together with the DATBMR registers they cache translation entries used for translating virtual to physical address. A virtual address is formed from the EA generated during a load/store operation, and the SR[CID] field. Together with the DATBMR registers and match logic they form a core part of the DMMU.

Table 8-13. IATBTR Field Descriptions

8.5 Address Translation Mechanism in 32-bit Implementations

Memory in an OpenRISC 1000 implementation with 32-bit effective addresses (EA) is divided into level 1 and level 2 pages. Translation is therefore based on two-level page table. However for virtual memory areas that do not need the smallest 8KB page granularity, only one level can be used.

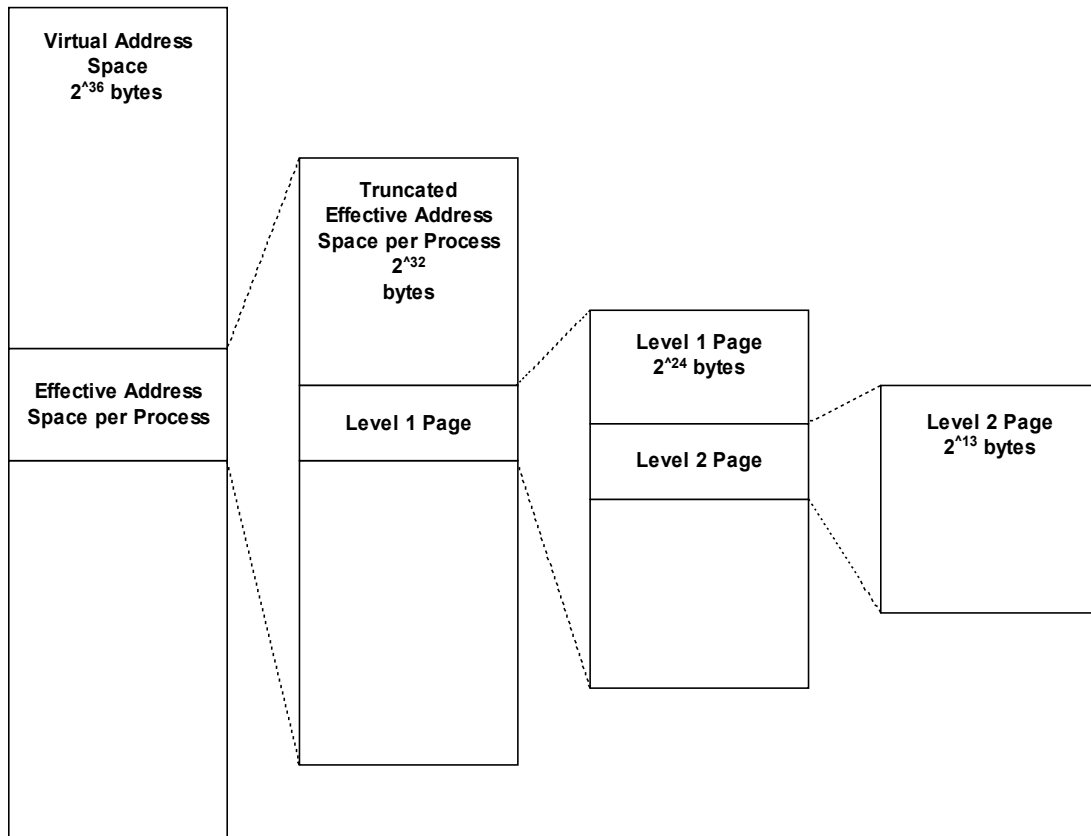

Figure 8-2. Memory Divided Into L1 and L2 pages

The first step in page address translation is to append the current SR[CID] bits as most significant bits to the 32-bit effective address, combining them into a 36-bit virtual address. This virtual address is then used to locate the correct page table entry (PTE) in the page tables in the memory. The physical page number is then extracted from the PTE and used in the physical address. Note that for increased performance, most processors implement on-chip translation lookaside buffers (TLBs) to cache copies of the recently-used PTEs.

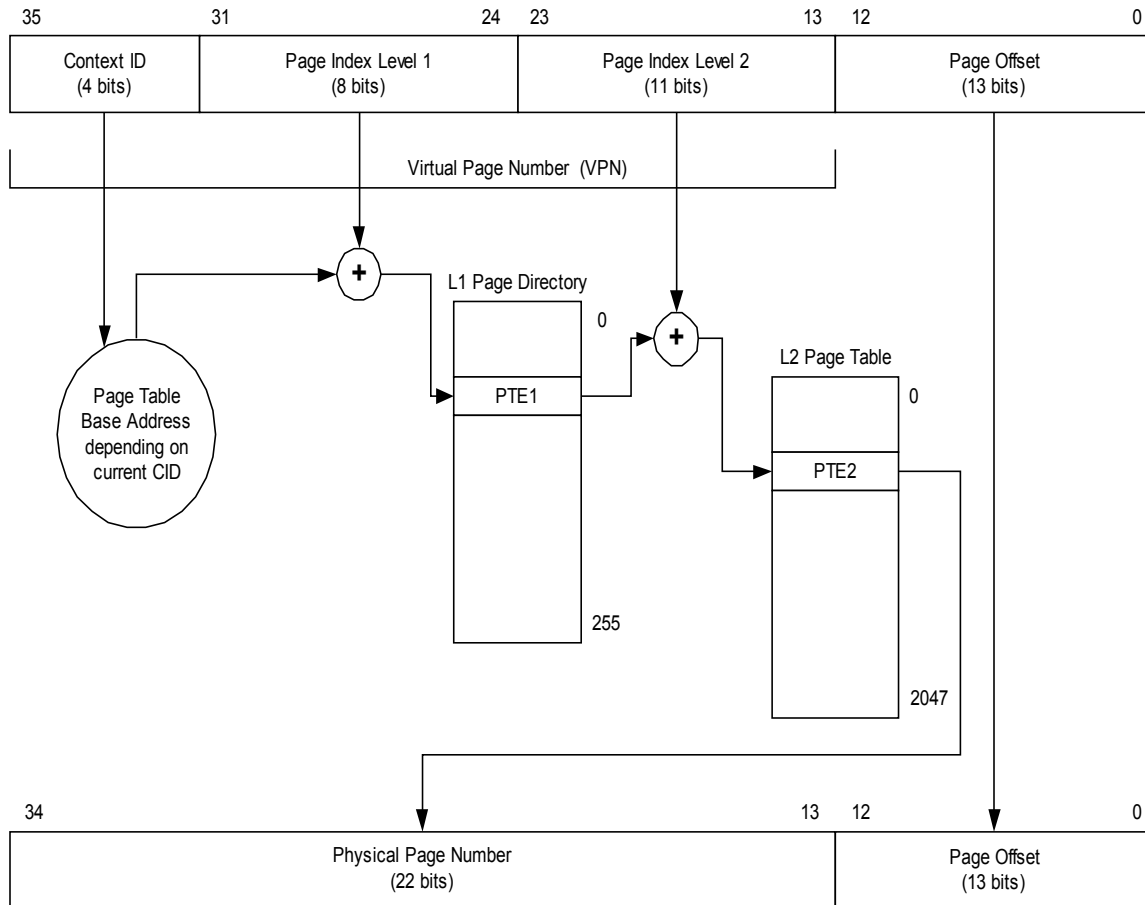

Figure 8-3. Address Translation Mechanism using Two-Level Page Table

Figure 8-3 shows an overview of the two-level page table translation of a virtual address to a physical address:

- ✓ Bits 35..32 of the virtual address select the page tables for the current context (process)
- ✓ Bits 31..24 of the virtual address correspond to the level 1 page number within the current context's virtual space. The L1 page index is used to index the L1 page directory and to retrieve the PTE from it, or together with the L2 page index to match for the PTE in on-chip TLBs.
- ✓ Bits 23..13 of the virtual address correspond to the level 2 page number within the current context's virtual space. The L2 page index is used to index the L2 page table and to retrieve the PTE from it, or together with the L1 page index to match for the PTE in on-chip TLBs.
- ✓ Bits 12..0 of the virtual address are the byte offset within the page; these are concatenated with the PPN field of the PTE to form the physical address used to access memory

The OpenRISC 1000 two-level page table translation also allows implementation of segments with only one level of translation. This greatly reduces memory requirements

for the page tables since large areas of unused virtual address space can be covered only by level 1 PTEs.

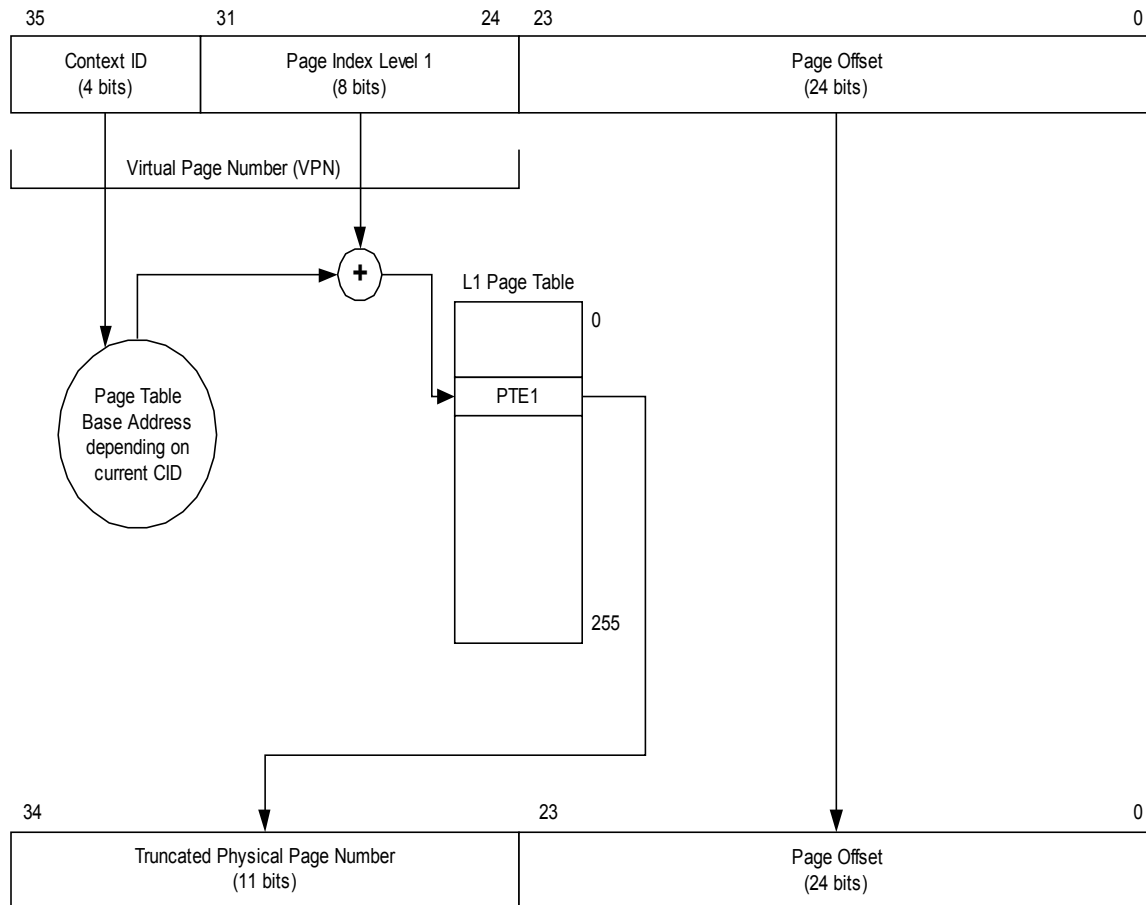

Figure 8-4. Address Translation Mechanism using only L1 Page Table

Figure 8-4 shows an overview of the one-level page table translation of a virtual address to physical address:

- ✓ Bits 35..32 of the virtual address select the page tables for the current context (process)
- ✓ Bits 31..24 of the virtual address correspond to the level 1 page number within the current context's virtual space. The L1 page index is used to index the L1 page table and to retrieve the PTE from it, or to match for the PTE in on-chip TLBs.
- ✓ Bits 23..0 of the virtual address are the byte offset within the page; these are concatenated with the truncated PPN field of the PTE to form the physical address used to access memory

8.6 Address Translation Mechanism in 64-bit Implementations

Memory in OpenRISC 1000 implementations with 64-bit effective addresses (EA) is divided into level 0, level 1 and level 2 pages. Translation is therefore based on three-level page table. However for virtual memory areas that do not need the smallest page granularity of 8KB, two level translation can be used.

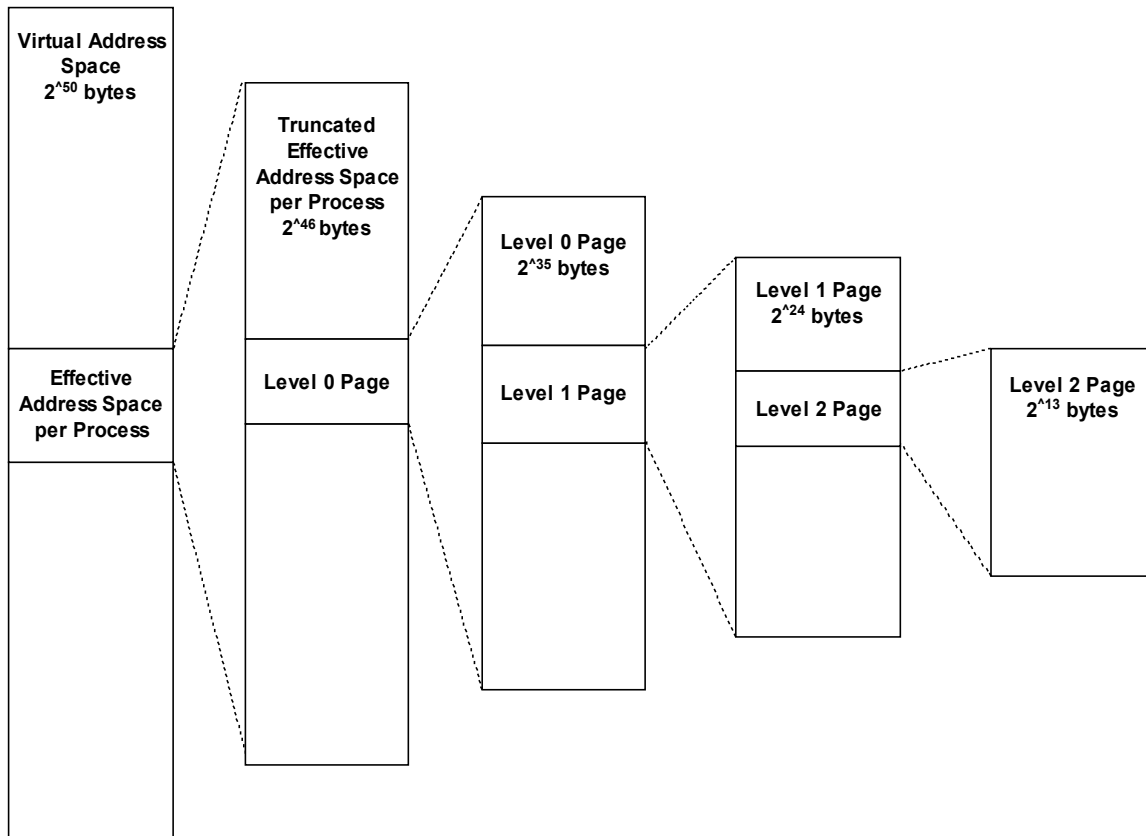

Figure 8-5. Memory Divided Into L0, L1 and L2 pages

The first step in page address translation is truncation of the 64-bit effective address into a 46-bit address. Then the current SR[CID] bits are appended as most significant bits. The 50-bit virtual address thus formed is then used to locate the correct page table entry (PTE) in the page tables in the memory. The physical page number is then extracted from the PTE and used in the physical address. Note that for increased performance, most processors implement on-chip translation lookaside buffers (TLBs) to cache copies of the recently-used PTEs.

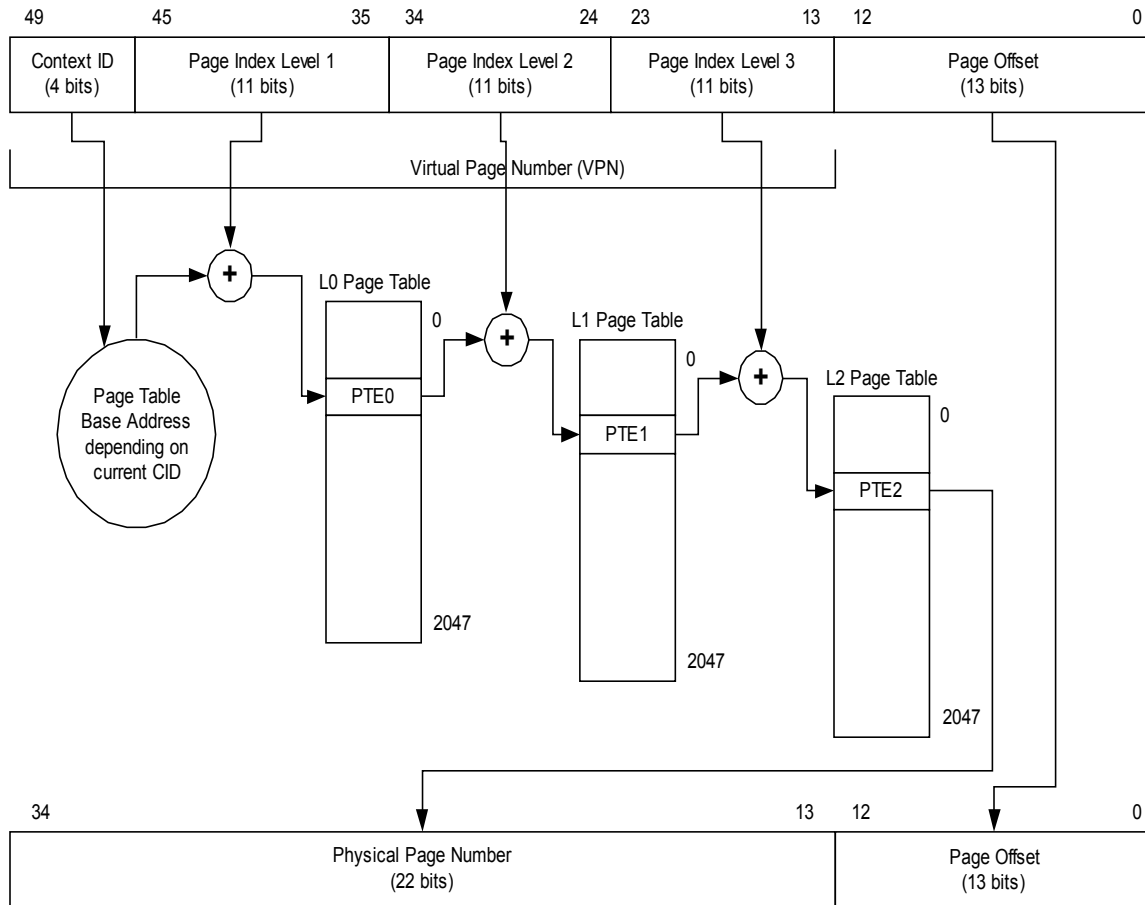

Figure 8-6. Address Translation Mechanism using Three-Level Page Table

Figure 8-6 shows an overview of the three-level page table translation of a virtual address to physical address:

- ✓ Bits 49..46 of the virtual address select the page tables for the current context (process)
- ✓ Bits 45..35 of the virtual address correspond to the level 0 page number within current context's virtual space. The L0 page index is used to index the L0 page directory and to retrieve the PTE from it, or together with the L1 and L2 page indexes to match for the PTE in on-chip TLBs.
- ✓ Bits 34..24 of the virtual address correspond to the level 1 page number within the current context's virtual space. The L1 page index is used to index the L1 page directory and to retrieve the PTE from it, or together with the L0 and L2 page indexes to match for the PTE in on-chip TLBs.
- ✓ Bits 23..13 of the virtual address correspond to the level 2 page number within the current context's virtual space. The L2 page index is used to index the L2 page table and to retrieve the PTE from it, or together with the L0 and L1 page indexes to match for the PTE in on-chip TLBs.

- ✓ Bits 12..0 of the virtual address are the byte offset within the page; these are concatenated with the truncated PPN field of the PTE to form the physical address used to access memory

The OpenRISC 1000 three-level page table translation also allows implementation of large segments with two levels of translation. This greatly reduces memory requirements for the page tables since large areas of unused virtual address space can be covered only by level 1 PTEs.

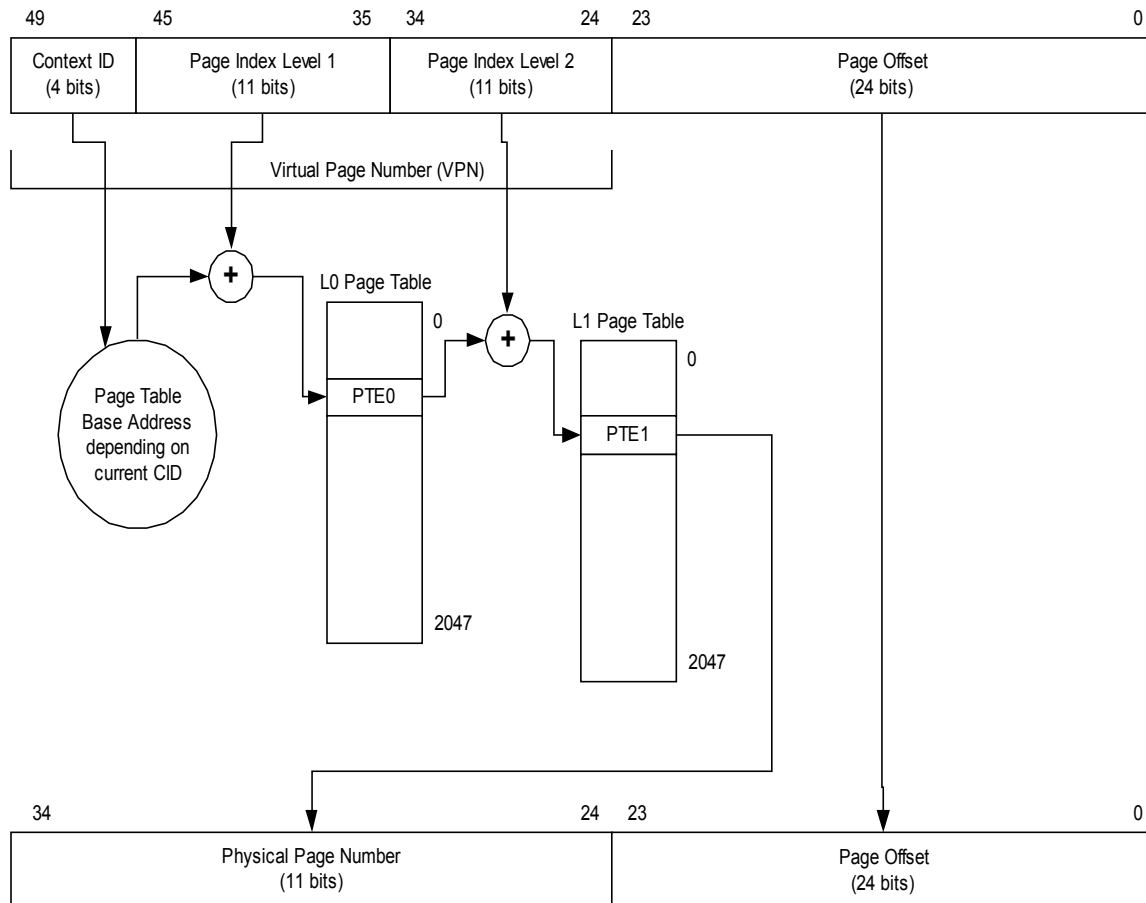

Figure 8-7. Address Translation Mechanism using Two-Level Page Table

Figure 8-7 shows an overview of the two-level page table translation of a virtual address to physical address:

- ✓ Bits 49..46 of the virtual address select the page tables for the current context (process)
- ✓ Bits 45..35 of the virtual address correspond to the level 0 page number within the current context's virtual space. The L0 page index is used to index the L0 page directory and to retrieve the PTE from it, or together with the L1 page index to match for the PTE in on-chip TLBs.

- ✓ Bits 34..24 of the virtual address correspond to the level 1 page number within the current context's virtual space. The L1 page index is used to index the L1 page table and to retrieve the PTE from it, or together with the L0 page index to match for the PTE in on-chip TLBs.
- ✓ Bits 23..0 of the virtual address are the byte offset within the page; these are concatenated with the truncated PPN field of the PTE to form the physical address used to access memory

8.7 Memory Protection Mechanism

After a virtual address is determined to be within a page covered by the valid PTE, the access is validated by the memory protection mechanism. If this protection mechanism prohibits the access, a page fault exception is generated.

The memory protection mechanism allows selectively granting read access, write access or execute access for both supervisor and user modes. The page protection mechanism provides protection at all page level granularities.

Protection attribute	Meaning
DMMUPR[SREx]	Enable load operations in supervisor mode to the page.
DMMUPR[SWEx]	Enable store operations in supervisor mode to the page.
IMMUPR[SXEx]	Enable execution in supervisor mode of the page.
DMMUPR[UREx]	Enable load operations in user mode to the page.
DMMUPR[UWEx]	Enable store operations in user mode to the page.
IMMUPR[UXEx]	Enable execution in user mode of the page.

Table 8-14. Protection Attributes

Table 8-14 lists page protection attributes defined in MMU protection registers. For the individual page the appropriate strategy out of seven possible strategies programmed in MMU protection registers is selected with the PPI field of the PTE.

In OpenRISC 1000 processors that do not implement TLB/ATB reload in hardware, protection registers are not needed.

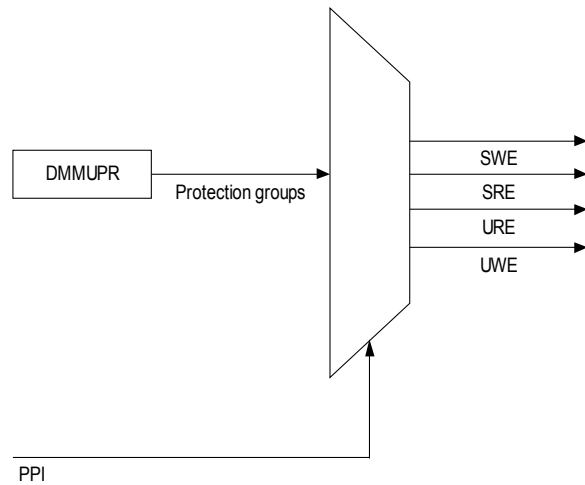

Figure 8-8. Selection of Page Protection Attributes for Data Accesses

Figure 8-9. Selection of Page Protection Attributes for Instruction Fetch Accesses

8.8 Page Table Entry Definition

Page table entries (PTEs) are generated and placed in page tables in memory by the operating system. A PTE is 32 bits wide and is the same for 32-bit and 64-bit OpenRISC 1000 processor implementations.

A PTE translates a virtual memory area into a physical memory area. How much virtual memory is translated depends on which level the PTE resides. PTEs are either in page directories with L bit zeroed or in page tables with L bit set. PTEs in page directories point to next level page directory or to final page table that contains PTEs for actual address translation.

**Figure 8-10. Page Table Entry Format**

CC	Cache Coherency 0 Data cache coherency is not enforced for this page 1 Data cache coherency is enforced for this page
CI	Cache Inhibit 0 Cache is enabled for this page 1 Cache is disabled for this page
WBC	Write-Back Cache 0 Data cache uses write-through strategy for data from this page 1 Data cache uses write-back strategy for data from this page
WOM	Weakly-Ordered Memory 0 Strongly-ordered memory model for this page 1 Weakly-ordered memory model for this page
A	Accessed 0 Page was not accessed 1 Page was accessed
D	Dirty 0 Page was not modified 1 Page was modified
PPI	Page Protection Index 0 PTE is invalid 1-7 Selects a group of six bits from a set of seven protection attribute groups in xMMUCR
L	Last 0 PTE from page directory pointing to next page directory/table 1 Last PTE in a linked form of PTEs (describing the actual page)
PPN	Physical Page Number 0-N Number of the physical frame in memory

Table 8-15. PTE Field Descriptions

8.9 Page Table Search Operation

An implementation may choose to implement the page table search operation in either hardware or software. For all page table search operations data addresses are untranslated (i.e. the effective and physical base address of the page table are the same).

When implemented in software, two TLB miss exceptions are used to handle TLB reload operations. Also, the software is responsible for maintaining accessed and dirty bits in the page tables.

8.10 Page History Recording

The accessed (A) and dirty (D) bits reside in each PTE and keep information about the history of the page. The operating system uses this information to determine which areas of the main memory to swap to the disk and which areas of the memory to load back to the main memory (demand-paging).

The accessed (A) bit resides both in the PTE in page table and in the copy of PTE in the TLB. Each time the page is accessed by a load, store or instruction fetch operation, the accessed bit is set.

If the TLB reload is performed in software, then the software must also write back the accessed bit from the TLB to the page table.

In cases when access operation to the page fails, it is not defined whether the accessed bit should be set or not. Since the accessed bit is merely a hint to the operating system, it is up to the implementation to decide.

It is up to the operating system to determine when to explicitly clear the accessed bit for a given page.

The dirty (D) bit resides in both the PTE in page table and in the copy of PTE in the TLB. Each time the page is modified by a store operation, the dirty bit is set.

If TLB reload is performed in software, then the software must also write back the dirty bit from the TLB to the page table.

In cases when access operation to the page fails, it is not defined whether the dirty bit should be set or not. Since the dirty bit is merely a hint to the operating system, it is up to the implementation to decide. However implementation or TLB reload software must check whether page is actually writable before setting the dirty bit.

It is up to the operating system to determine when to explicitly clear the dirty bit for a given page.

8.11 Page Table Updates

Updates to the page tables include operations like adding a PTE, deleting a PTE and modifying a PTE. On multiprocessor systems exclusive access to the page table must be assured before it is modified.

TLBs are noncoherent caches of the page tables and must be maintained accordingly. Explicit software synchronization between TLB and page tables is required so that page tables and TLBs remain coherent.

Since the processor reloads PTEs even during updates of the page table, special care must be taken when updating page tables so that the processor does not accidentally use half modified page table entries.

9 Cache Model & Cache Coherency

This chapter describes the OpenRISC 1000 cache model and architectural control to maintain cache coherency in multiprocessor environment.

Note that this chapter describes the cache model and cache coherency mechanism from the perspective of the programming model. As such, it describes the cache management principles, the cache coherency mechanisms and the cache control registers. The hardware implementation details that are invisible to the OpenRISC 1000 programming model, such as cache organization and size, are not contained in the architectural definition.

The function of the cache management registers depends on the implementation of the cache(s) and the setting of the memory/cache access attributes. For a program to execute properly on all OpenRISC 1000 processor implementations, software should assume a Harvard cache model. In cases where a processor is implemented without a cache, the architecture guarantees that writing to cache registers will not halt execution. For example a processor without cache should simply ignore writes to cache management registers. A processor with a Stanford cache model should simply ignore writes to instruction cache management registers. In this manner, programs written for separate instruction and data caches will run on all compliant implementations.

9.1 Cache Special-Purpose Registers

Table 9-1 summarizes the registers that the operating system uses to manage the cache(s).

For implementations that have unified cache, registers that control the data and instruction caches are merged and available at the same time both as data and instruction cache registers.

GRP #	REG #	REG NAME	USER MODE	SUPV MODE	DESCRIPTION
3	0	DCCR	–	R/W	Data Cache Control Register
3	1	DCBPR	W	W	Data Cache Block Prefetch Register
3	2	DCBFR	W	W	Data Cache Block Flush Register
3	3	DCBIR	–	W	Data Cache Block Invalidate Register
3	4	DCBWR	W	W	Data Cache Block Write-back Register
3	5	DCBLR	-	W	Data Cache Block Lock Register
4	0	ICCR	–	R/W	Instruction Cache Control Register
4	1	ICBPR	W	W	Instruction Cache Block PreFetch Register

GRP #	REG #	REG NAME	USER MODE	SUPV MODE	DESCRIPTION
4	2	ICBIR	W	W	Instruction Cache Block Invalidate Register
4	3	ICBLR	-	W	Instruction Cache Block Lock Register

Table 9-1. Cache Registers

9.1.1 Data Cache Control Register

The data cache control register is a 32-bit special-purpose register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

The DCCR controls the operation of the data cache.

Bit	31-8	7-0
Identifier	Reserved	EW
Reset	X	0
R/W	R	R/W

EW	Enable Ways 0000 0000 All ways disabled/locked ... 1111 1111 All ways enabled/unlocked
----	---

Table 9-2. DCCR Field Descriptions

If data cache does not implement way locking, the DCCR is not required to be implemented.

9.1.2 Instruction Cache Control Register

The instruction cache control register is a 32-bit special-purpose register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

The ICCR controls the operation of the instruction cache.

Bit	31-8	7-0
Identifier	Reserved	EW
Reset	X	0
R/W	R	R/W

EW	Enable Ways 0000 0000 All ways disabled/locked ... 1111 1111 All ways enabled/unlocked
----	---

Table 9-3. ICCR Field Descriptions

If the instruction cache does not implement way locking, the ICCR is not required to be implemented.

9.2 Cache Management

This section describes special-purpose cache management registers for both data and instruction caches.

Memory accesses caused by cache management are not recorded (unlike load or store instructions) and cannot invoke any exception.

Instruction caches do not need to be coherent with the memory or caches of other processors. Software must make the instruction cache coherent with modified instructions in the memory. A typical way to accomplish this is:

1. Data cache block write-back (update of the memory)
2. l.csync (wait for update to finish)
3. Instruction cache block invalidate (clear instruction cache block)
4. Flush pipeline

9.2.1 Data Cache Block Prefetch (Optional)

The data cache block prefetch register is an optional special-purpose register accessible with the l.mtspr/l.mfspr instructions in both user and supervisor modes. It is 32 bits wide in 32-bit implementations and 64 bits wide in 64-bit implementations. An implementation may choose not to implement this register and ignore all writes to this register.

The DCBPR is written with the effective address and the corresponding block from memory is prefetched into the cache. Memory accesses are not recorded (unlike load or store instructions) and cannot invoke any exception.

A data cache block prefetch is used strictly for improving performance.

Bit	31-0
Identifier	EA
Reset	0
R/W	Write Only

EA	Effective Address EA that targets byte inside cache block
----	--

Table 9-4. DCBPR Field Descriptions

9.2.2 Data Cache Block Flush

The data cache block flush register is a special-purpose register accessible with the `l.mtspr/l.mfspr` instructions in both user and supervisor modes. It is 32 bits wide in 32-bit implementations and 64 bits wide in 64-bit implementations.

The DCBFR is written with the effective address. If coherency is required then the corresponding:

- ✓ Unmodified data cache block is invalidated in all processors.
- ✓ Modified data cache block is written back to the memory and invalidated in all processors.
- ✓ Missing data cache block in the local processor causes that modified data cache block in other processor is written back to the memory and invalidated. If other processors have unmodified data cache block, it is just invalidated in all processors.

If coherency is not required then the corresponding:

- ✓ Unmodified data cache block in the local processor is invalidated.
- ✓ Modified data cache block is written back to the memory and invalidated in local processor.
- ✓ Missing cache block in the local processor does not cause any action.

Bit	31-0
Identifier	EA

EA	Effective Address EA that targets byte inside cache block
----	--

Table 9-5. DCBFR Field Descriptions

9.2.3 Data Cache Block Invalidate

The data cache block invalidate register is a special-purpose register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode. It is 32 bits wide in 32-bit implementations and 64 bits wide in 64-bit implementations.

The DCBIR is written with the effective address. If coherency is required then the corresponding:

- ✓ Unmodified data cache block is invalidated in all processors.
- ✓ Modified data cache block is invalidated in all processors.

- ✓ Missing data cache block in the local processor causes that data cache blocks in other processors are invalidated.

If coherency is not required then corresponding:

- ✓ Unmodified data cache block in the local processor is invalidated.
- ✓ Modified data cache block in the local processor is invalidated.
- ✓ Missing cache block in the local processor does not cause any action.

9.2.4 Data Cache Block Write-Back

The data cache block write-back register is a special-purpose register accessible with the `l.mtspr/l.mfspr` instructions in both user and supervisor modes. It is 32 bits wide in 32-bit implementations and 64 bits wide in 64-bit implementations.

The DCBWR is written with the effective address. If coherency is required then the corresponding data cache block in any of the processors is written back to memory if it was modified. If coherency is not required then the corresponding data cache block in the local processor is written back to memory if it was modified.

9.3 Cache/Memory Coherency

The primary role of the cache coherency system is to synchronize cache content with other caches and with the memory and to provide the same image of the memory to all devices using the memory.

The architecture provides several features to implement cache coherency. In systems that do not provide cache coherency with the PTE attributes (because they do not implement a memory management unit), it may be provided through explicit cache management.

Cache coherency in systems with virtual memory can be provided on a page-by-page basis with PTE attributes. The attributes are:

- ✓ Cache Coherent (CC Attribute)
- ✓ Caching-Inhibited (CI Attribute)
- ✓ Write-Back Cache (WBC Attribute)

When the memory/cache attributes are changed, it is imperative that the cache contents should reflect the new attribute settings. This usually means that cache blocks must be flushed or invalidated.

9.3.1 Pages Designated as Cache Coherent Pages

This attribute improves performance of the systems where cache coherency is performed with hardware and is relatively slow. Memory pages that do not need cache coherency are marked with $CC=0$ and only memory pages that need cache coherency are marked with $CC=1$. When an access to shared resource is made, the local processor will assert some kind of cache coherency signal and other processors will respond if they have a copy of the target location in their caches.

To improve performance of uniprocessor systems, memory pages should not be designated as $CC=1$.

9.3.2 Pages Designated as Caching-Inhibited Pages

Memory accesses to memory pages designated with $CI=1$ are always performed directly into the main memory, bypassing all caches. Memory pages designated with $CI=1$ are not loaded into the cache and the target content should never be available in the cache. To prevent any accident copy of the target location in the cache, whenever the operating system sets a memory page to be caching-inhibited, it should flush the corresponding cache blocks.

Multiple accesses may be merged into combined accesses except when individual accesses are separated by **l.msyc** or **l.csyc** or **l.psyc**.

9.3.3 Pages Designated as Write-Back Cache Pages

Store accesses to memory pages designated with $WBC=0$ are performed both in data cache and memory. If a system uses multilevel hierarchy caches, a store must be performed to at least the depth in the memory hierarchy seen by other processors and devices.

Multiple stores may be merged into combined stores except when individual stores are separated by **l.msync** or **l.sync** or **l.psync**. A store operation may cause any part of the cache block to be written back to main memory.

Store accesses to memory pages designated with $WBC=1$ are performed only to the local data cache. Data from the local data cache can be copied to other caches and to main memory when copy-back operation is required. $WBC=1$ improves system performance, however it requires cache snooping hardware support in data cache controllers to guarantee cache coherency.

10 Debug Unit (Optional)

This chapter describes the OpenRISC 1000 debug facility. The debug unit assists software developers in debugging their systems. It provides support for watchpoints, breakpoints and program-flow control registers.

Watchpoints and breakpoint are events triggered by program- or data-flow matching the conditions programmed in the debug registers. Watchpoints do not interfere with the execution of the program-flow except indirectly when they cause a breakpoint. Watchpoints can be counted by Performance Counters Unit.

Breakpoint, unlike watchpoints, also suspends execution of the current program-flow and start trap exception processing. Breakpoint is optional consequence of watchpoints.

10.1 Features

The OpenRISC 1000 architecture defines eight sets of debug registers. Additional debug register sets can be defined by the implementation itself. The debug unit is optional and the presence of an implementation is indicated by the UPR[DUP] bit.

- ✓ Optional implementation
- ✓ Eight architecture defined sets of debug value/compare registers
- ✓ Match signed/unsigned conditions on instruction fetch EA, load/store EA and load/store data
- ✓ Combining match conditions for complex watchpoints
- ✓ Watchpoints can be counted by Performance Counters Unit
- ✓ Watchpoints can generate a breakpoint (trap exception)
- ✓ Counting watchpoints for generation of additional watchpoints

DVR/DCR pairs are used to compare instruction fetch or load/store EA and load/store data to the value stored in DVRs. Matches can be combined into more complex matches and used for generation of watchpoints. Watchpoints can be counted and reported as breakpoint.

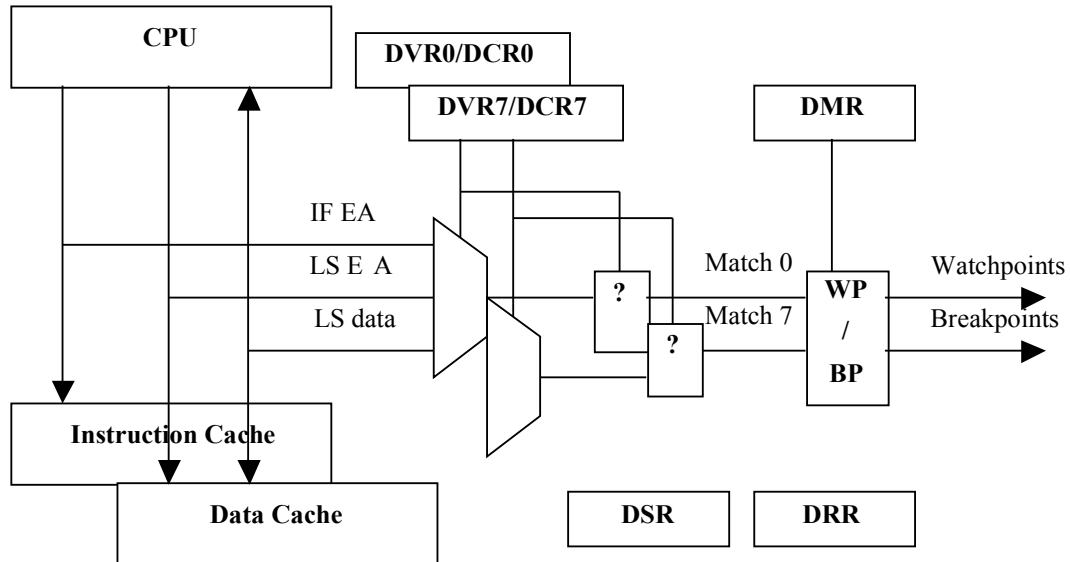

Figure 10-1. Block Diagram of Debug Support

10.2 Debug Value Registers (DVR0-DVR7)

The debug value registers are 32-bit special-purpose supervisor-level registers accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

The DVRs are programmed with the watchpoint addresses or data by the resident debug software or by the development interface. Their value is compared to the fetch or load/store EA or to the load/store data according to the corresponding DCR. Based on the settings of the corresponding DCR a watchpoint is generated.

10.5 Debug Mode Register 2(DMR2)

The debug mode register 2 is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

The DMR2 is programmed with the watchpoint/breakpoint settings that define which watchpoints generate a breakpoint and which watchpoint counters are enabled. When a breakpoint happens WBS provides information which watchpoint or several watchpoints caused breakpoint condition. WBS bits are sticky and should be cleared by writing 0 to them every time a breakpoint condition is processed. DMR2 is set by the resident debug software or by the development interface.

Table 10-4. DMR2 Field Descriptions

10.6 Debug Watchpoint Counter Register (DWCR0-DWCR1)

The debug watchpoint counter registers are 32-bit special-purpose supervisor-level registers accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

The DWCRs contain 16-bit counters that count watchpoints programmed in the DMR. The value in a DWCR can be accessed by the resident debug software or by the development interface. DWCRs also contain match values. When a counter reaches the match value, a watchpoint is generated.

Bit	31-16	15-0
Identifier	MATCH	COUNT
Reset	0	0
R/W	R/W	R/W

COUNT	Number of watchpoints programmed in DMR N 16-bit counter of generated watchpoints assigned to this counter
MATCH	N 16-bit value that when matched generates a watchpoint

Table 10-5. DWCR Field Descriptions

10.7 Debug Stop Register (DSR)

The debug stop register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

The DSR specifies which exceptions cause the core to stop the execution of the exception handler and turn over control to development interface. It can be programmed by the resident debug software or by the development interface.

10.8 Debug Reason Register (DRR)

The debug reason register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

The DRR specifies which event caused the core to stop the execution of program flow and turned control over to the development interface. It should be cleared by the resident debug software or by the development interface.

Table 10-7. DRR Field Descriptions

11 Performance Counters Unit (Optional)

This chapter describes the OpenRISC 1000 performance counters facility. Performance counters can be used to count predefined events such as L1 instruction or data cache misses, branch instructions, pipeline stalls etc.

Data from the Performance Counters Unit can be used for the following:

- ✓ To improve performance by developing better application level algorithms, better optimized operating system routines and for improvements in the hardware architecture of these systems (e.g. memory subsystems).
- ✓ To improve future OpenRISC implementations and add future enhancements to the OpenRISC architecture.
- ✓ To help system developers debug and test their systems.

11.1 Features

The OpenRISC 1000 architecture defines eight performance counters. Additional performance counters can be defined by the implementation itself. The Performance Counters Unit is optional and the presence of an implementation is indicated by the UPR[PCUP] bit.

- ✓ Optional implementation.
- ✓ Eight architecture defined performance counters
- ✓ Eight custom performance counters
- ✓ Programmable counting conditions.

11.2 Performance Counters Count Registers (PCCR0-PCCR7)

The performance counters count registers are 32-bit special-purpose supervisor-level registers accessible with the l.mtspr/l.mfspr instructions in supervisor mode. Read access in user mode is possible, if it is enabled in SR[SUMRA].

They are counters of the events programmed in the PCMR registers.

Bit	31-0

Table 11-2. PCMR Field Descriptions

12 Power Management (Optional)

This chapter describes the OpenRISC 1000 power management facility. The power management facility is optional and implementation may choose which features to implement, and which not. UPR[PMP] indicates whether power management is implemented or not.

Note that this chapter describes the architectural control of power management from the perspective of the programming model. As such, it does not describe technology specific optimizations or implementation techniques.

12.1 Features

The OpenRISC 1000 architecture defines five architectural features for minimizing power consumption:

- ✓ slow down feature
- ✓ doze mode
- ✓ sleep mode
- ✓ suspend mode
- ✓ dynamic clock gating feature

The slow down feature takes advantage of the low-power dividers in external clock generation circuitry to enable full functionality, but at a lower frequency so that power consumption is reduced.

The slow down feature is software controlled with the 4-bit value in PMR[SDF]. A lower value specifies higher expected performance from the processor core. Whether this value controls a processor clock frequency or some other implementation specific feature is irrelevant to the controlling software. Usually PMR[SDF] is dynamically set by the operating system's idle routine, that monitors the usage of the processor core.

When software initiates the doze mode, software processing on the core suspends. The clocks to the processor internal units are disabled except to the internal tick timer and programmable interrupt controller. However other on-chip blocks (outside of the processor block) can continue to function as normal.

The processor should leave doze mode and enter normal mode when a pending interrupt occurs.

In sleep mode, all processor internal units are disabled and clocks gated. Optionally, an implementation may choose to lower the operating voltage of the processor core.

The processor should leave sleep mode and enter normal mode when a pending interrupt occurs.

In suspend mode, all processor internal units are disabled and clocks gated. Optionally, an implementation may choose to lower the operating voltage of the processor core.

The processor enters normal mode when it is reset. Software may implement a reset exception handler that refreshes system memory and updates the RISC with the state prior to the suspension.

If enabled, the clock-gating feature automatically disables clock subtrees to major processor internal units on a clock cycle basis. These blocks are usually the CPU, FPU/VU, IC, DC, IMMU and DMMU. This feature can be used in a combination with other power management features and low-power modes.

Cache or MMU blocks that are already disabled when software enables this feature, have completely disabled clock subtrees until clock gating is disabled or until the blocks are again enabled.

12.2 Power Management Register (PMR)

The power management register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

PMR is used to enable or disable power management features and modes.

Bit	31-7	7	6	5	4	3-0

DCGE	Dynamic Clock Gating Enable 0 Dynamic clock gating not enabled 1 Dynamic clock gating enabled
SUME	Suspend Mode Enable 0 Suspend mode not enabled 1 Suspend mode enabled

Table 12-1. PMR Field Descriptions

13 Programmable Interrupt Controller (Optional)

This chapter describes the OpenRISC 1000 level one programmable interrupt controller. The interrupt controller facility is optional and an implementation may choose whether or not to implement it. If it is not implemented, interrupt input is directly connected to interrupt exception inputs. UPR[PICP] specifies whether the programmable interrupt controller is implemented or not.

The Programmable Interrupt Controller has two special-purpose registers and 32 maskable interrupt inputs. If implementation requires permanent unmasked interrupt inputs, it can use interrupt inputs [1:0] and PICMR[1:0] should be fixed to one.

13.1 Features

The OpenRISC 1000 architecture defines an interrupt controller facility with up to 32 interrupt inputs:

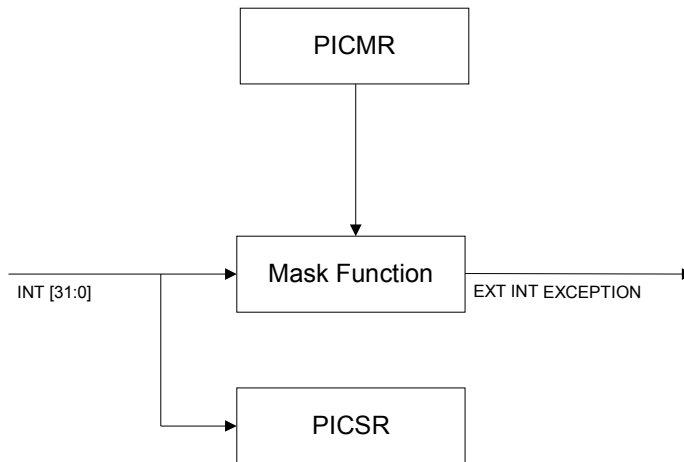

Figure 13-1. Programmable Interrupt Controller Block Diagram

13.2 PIC Mask Register (PICMR)

The interrupt controller mask register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

PICMR is used to mask or unmask 32 programmable interrupt sources.

-----	---

Table 13-1. PICMR Field Descriptions

13.3 PIC Status Register (PICSR)

The interrupt controller status register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

PICSR is used to determine the status of each PIC interrupt input. PIC can support level-triggered interrupts or combination of level-triggered and edge-triggered. Most implementations today only support level-triggered interrupts.

For level-triggered implementations bits in PICSR simply represent level of interrupt inputs. Interrupts are cleared by taking appropriate action at the device to negate the source of the interrupt. Writing a '1' or a '0' to bits in the PICSR that reflect a level-triggered source must have no effect on PICSR content.

The atomic way to clear an interrupt source which is edge-triggered is by writing a '1' to the corresponding bit in the PICSR. This will clear the underlying latch for the edge-triggered source. Writing a '0' to the corresponding bit in the PICSR has no effect on the underlying latch.

Bit	31-0

----	--

Table 13-2. PICSR Field Descriptions

14 Tick Timer Facility (Optional)

This chapter describes the OpenRISC 1000 tick timer facility. It is optional and an implementation may choose whether or not to implement it. UPR[TTP] specifies whether or not the tick timer facility is present.

The Tick Timer is used to schedule operating system and user tasks on regular time basis or as a high precision time reference.

The Tick Timer facility is enabled with TTMR[M]. TTCR is incremented with each clock cycle and a tick timer interrupt can be asserted whenever the lower 28 bits of TTCR match TTMR[TP] and TTMR[IE] is set.

TTCR restarts counting from zero when a match event happens and TTMR[M] is 0x1. If TTMR[M] is 0x2, TTCR is stopped when match event happens and TTCR must be changed to start counting again. When TTMR[M] is 0x3, TTCR keeps counting even when match event happens.

14.1 Features

The OpenRISC 1000 architecture defines a tick timer facility with the following features:

- ✓ Maximum timer count of 2^{32} clock cycles
- ✓ Maximum time period of 2^{28} clock cycles between interrupts
- ✓ Maskable tick timer interrupt
- ✓ Single run, restartable counter, or continues counter

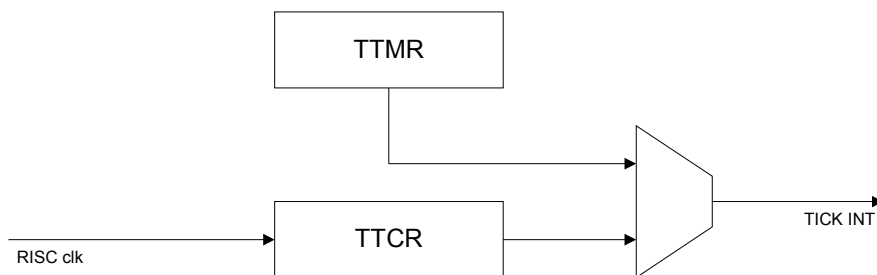

Figure 14-1. Tick Timer Block Diagram

14.2 Timer interrupts

A timer interrupt will happen everytime TTMR[IE] bit is set and TTMR[TP] matches the lower 28-bits of the TTCR SPR, the top 4 bits are ignored for the comparison. When an interrupt is pending the TTMR[IP] bit will be set and the interrupt will be asserted to the cpu core until it is cleared by writing a 0 to the TTMR[IP] bit. However, if the TTMR[IE] bit was not set when a match condition occurred no interrupt will be asserted and the TTMR[IP] bit won't be set unless it has not been cleared from a previous interrupt. The TTMR[IE] bit is not meant as a mask bit, SR[TEE] is provided for that purpose.

14.3 Timer modes

It is up to the programmer to ensure that the TTCR SPR is set to a sane value before the timer mode is programmed. When the timing mode is programmed into the timer by setting TTMR[M], the TTCR SPR is not preset to any predefined value, including 0. If the lower 28-bits of the TTCR SPR is numerically greater than what was programmed into TTMR[TP] then the timer will only assert the timer interrupt when the lower 28-bits of the TTCR SPR have wrapped around to 0 and counted up to the match value programmed into TTMR[TP].

14.3.1 Disabled timer

In this mode the timer does not increment the TTCR spr. Though note that the timer interrupt is independent from the timer mode and as such the timer interrupt is not disabled when the timer is disabled.

14.3.2 Auto-restart timer

When the timer is set to auto-restart mode, the timer will reset the TTCR spr to 0 as soon as the lower 28-bits of the TTCR spr match TTMR[TP] and the timer interrupt will be asserted to the cpu core if the TTMR[IE] bit has been set.

14.3.3 One-shot timer

In one-shot timing mode, the timer stops counting as soon as a match condition has been reached. Although the timer has in effect been disabled (and can't be restarted by writing to the TTCR spr) the TTMR[M] bits shall still indicate that the timer is in one-shot mode and not that it has been disabled. Care should be taken that the timer interrupt has been masked (or disabled) after the match condition has been reached, or else the cpu core will get a spurious timer interrupt.

14.3.4 Continuous timer

In the event that a match condition has been reached, the counter does not stop but rather keeps counting from the value of the TTCR spr and the timer interrupt will be asserted if the TTMR[IE] bit has been set.

14.4 Tick Timer Mode Register (TTMR)

The tick timer mode register is a 32-bit special-purpose supervisor-level register accessible with the l.mtspr/l.mfspr instructions in supervisor mode.

The TTMR is programmed with the time period of the tick timer as well as with the mode bits that control operation of the tick timer.

15 OpenRISC 1000 Implementations

15.1 Overview

Implementations of the OpenRISC 1000 architecture come in different configurations and version releases.

Version and unit present registers both identify the model, version and its configuration. Detailed configuration for some units is available in configuration registers.

An operating system can read VR, UPR and the configuration registers, and adjust its own operation if required. Operating systems ported on a particular OpenRISC version should run on different configurations of this version without modifications.

15.2 Version Register (VR)

The version register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

It identifies the version (model) and revision level of the OpenRISC 1000 processor. It also specifies the possible template on which this implementation is based.

This register is deprecated, and the AVR and VR2 SPR should be used to determine more accurately the version information.

Bit	31-24	23-16	15-7	6	5-0
Identifier	VER	CFG	Reserved	UVRP	REV
Reset	-	-	x	-	-
R/W	R	R	R	R	R

REV	Revision 0..63 A 6-bit number that identifies various releases of a particular version. This number is changed for each revision of the device.
UVRP	Updated Version Registers Present A bit indicating that the AVR and VR2 SPRs are available and should be used to determine version information.

CFG	<p style="text-align: center;">Configuration Template</p> <p>0..99 An 8-bit number that identifies particular configuration. However this is just for operating systems that do not use information provided by configuration registers and thus are not truly portable across different configurations of one implementation version.</p> <p>Configurations that do implement configuration registers must have their CFG smaller than 50 and configurations that do not implement configuration registers must have their CFG 50 or bigger.</p>
VER	<p style="text-align: center;">Version</p> <p>0x10..0x19 An 8-bit number that identifies a particular processor version and version of the OpenRISC architecture. Values below 0x10 and above 0x19 are illegal for OpenRISC 1000 processor implementations.</p>

Table 15-1. VR Field Descriptions

15.3 Unit Present Register (UPR)

The unit present register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

It identifies the present units in the processor. It has a bit for each possible unit or functionality. The lower sixteen bits identify the presence of units defined in the OpenRISC 1000 architecture. The upper sixteen bits define the presence of custom units.

Table 15-7. ICCFGR Field Descriptions

15.9 Debug Configuration Register (DCFGR)

The debug configuration register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

It specifies debug unit capabilities and configuration.

Bit	31-4	3	2-0
Identifier	Reserved	WPCI	NDP
Reset	-	-	-
R/W	R	R	R

NDP	Number of Debug Pairs 0 Debug unit has one DCR/DVR pair ... 7 Debug unit has eight DCR/DVR pairs
WPCI	Watchpoint Counters Implemented 0 Watchpoint counters not implemented 1 Watchpoint counters implemented

Table 15-8. DCFGR Field Descriptions

15.10 Performance Counters Configuration Register (PCCFGR)

The performance counters configuration register is a 32-bit special-purpose supervisor-level register accessible with the `l.mtspr/l.mfspr` instructions in supervisor mode.

It specifies performance counters unit capabilities and configuration.

Bit	31-3	2-0
Identifier	Reserved	NPC
Reset	-	-
R/W	R	R

NPC	Number of Performance Counters 0 One performance counter ... 7 Eight performance counters
-----	--

Table 15-9. PCCFGR Field Descriptions

15.11 Version Register 2 (VR2)

The version register 2 is a 32-bit special-purpose supervisor-level register accessible with the `l.mfspr` instruction in supervisor mode.

It holds implementation-specific version information. It is intended to replace the VR register.

The value in the CPUID field should correspond to an implementation list held on the site which hosts this document. It is most likely that a master list will also be maintained at OpenCores.org.

Its presence is indicated by the UVRP bit in the Version Register (VR).

Bit	31-24	23-0
Identifier	CPUID	VER
Reset	-	-
R/W	R	R

CPUID	CPU Identification Number Implementation-specific identification number. Each implementation should have a unique identification number.
-------	---

VER	Version Implementation-specific version number. This field, if interpreted as an unsigned 24-bit number, should increase for each new version. The implementation reference manual should document the meaning of this value.
-----	--

Table 15-10. VR2 Field Descriptions

15.12 Architecture Version Register (AVR)

The architecture version register is a 32-bit special-purpose supervisor-level register accessible with the `l.mfspr` instruction in supervisor mode.

It indicates the most recent version the implementation contains features from. The implementation must at least implement an accurate set of feature-presence bits in the appropriate registers according to that version of the architecture spec, so the presence of each of that version's features can be checked. Its presence is indicated by the AVRP bit in the CPU Configuration Register (CPUCFGR).

Bit	31-24	23-16	15-8	7-0
Identifier	MAJ	MIN	REV	Reserved
Reset	-	-	-	-
R/W	R	R	R	R

MAJ	Major Architecture Version Number
MIN	Minor Architecture Version Number
REV	Architecture Revision Number

Table 15-11. AVR Field Descriptions

15.13 Exception Vector Base Address Register (EVBAR)

The architecture version register is a 32-bit special-purpose supervisor-level register accessible with the `l.mfspr`/`l.mtspr` instructions in supervisor mode.

This optional register can be used to apply an offset to the exception vector addresses. Its presence is indicated by the EVBARP bit in the CPU Configuration Register (CPUCFGR).

If `SR[EPH]` is set, this value is logically ORed with the offset that provides.

Bit	31-13	12-0
Identifier	EVBA	Reserved
Reset	-	-
R/W	R/W	R

EVBA	Exception Vector Base Address Location for the start of exception vectors. Its reset value is implementation-specific.
------	---

Table 15-12. EVBAR Field Descriptions

15.14 Arithmetic Exception Control Register (AECR)

The arithmetic exception control register is a 32-bit special-purpose supervisor-level register accessible with the `l.mfspr/ l.mtspr` instructions in supervisor mode.

This optional register can be used for fine-grained control over which arithmetic operations trigger overflow exceptions when the OVE bit is set in the Supervision Register (SR). Its presence is indicated by the AECSR bit in the CPU Configuration Register (CPUCFGR).

Bit	31-7	6	5
Identifier	Reserved	OVMACADDE	CYMACADDE
Reset	-	0	0
R/W	R	R/W	R/W

Reset	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W

CYADDE	Carry on Add Exception Carry flag set by unsigned overflow on integer addition and subtraction instructions causes exception
OVADDE	Overflow on Add Exception Overflow flag set by signed overflow on integer addition and subtraction instructions causes exception
CYMULE	Carry on Multiply Exception Carry flag set by unsigned overflow on integer multiplication instructions causes exception
OVMULE	Overflow on Multiply Exception Overflow flag set by signed overflow on integer multiplication instructions causes exception
DBZE	Divide By Zero Exception Overflow flag set by divide-by-zero on integer division instruction, or carry flag set by divide-by-zero on <code>l.divu</code> instruction, causes exception
CYMACADDE	Carry on MAC Addition Exception Carry flag set by unsigned overflow on integer addition stage of MAC instructions causes exception

OVMACADDE	Overflow on MAC Addition Exception Overflow flag set by signed overflow on integer addition stage of MAC instructions causes exception
-----------	---

Table 15-13. EACR Field Descriptions

15.15 Arithmetic Exception Status Register (AESR)

The arithmetic exception status register is a 32-bit special-purpose supervisor-level register accessible with the `l.mfspr/l.mtspr` instructions in supervisor mode.

This optional register indicates which arithmetic operations triggered an exception. The exceptions are triggered when the OVE bit is set in the Supervision Register (SR), and the overflow or carry flag is set according to any conditions with the corresponding bit set in the Arithmetic Exception Control Register (AECR).

This register will indicate which condition in the Arithmetic Exception Control Register (AECR) caused the exception by setting the corresponding bit. The bits can be cleared by writing '0' to them. The exception will occur due to the arithmetic operation, not due to the flags in this register being set, so failing to clear the flag before returning from exception with `SR[CY]` or `SR[OV]` set will not cause another exception..

Its presence is indicated by the AECSR bit in the CPU Configuration Register (CPUCFGR).

Bit	31-7	6	5
Identifier	Reserved	OVMACADDE	CYMACADDE
Reset	-	0	0
R/W	R	R/W	R/W

Bit	4	3	2	1	0
Identifier	DBZE	OVMULE	CYMULE	OVADDE	CYADDE
Reset	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W

CYADDE	Carry on Add Exception Carry flag set by unsigned overflow on integer addition and subtraction instructions caused exception
OVADDE	Overflow on Add Exception Overflow flag set by signed overflow on integer addition and subtraction instructions caused exception
CYMULE	Carry on Multiply Exception Carry flag set by unsigned overflow on integer multiplication instructions caused exception

OVMULE	Overflow on Multiply Exception Overflow flag set by signed overflow on integer multiplication instructions caused exception
DBZE	Divide By Zero Exception Overflow flag set by divide-by-zero on integer division instruction, or carry flag set by divide-by-zero on l.divu instruction, caused exception
CYMACADDE	Carry on MAC Addition Exception Carry flag set by unsigned overflow on integer addition stage of MAC instructions caused exception
OVMACADDE	Overflow on MAC Addition Exception Overflow flag set by signed overflow on integer addition stage of MAC instructions caused exception

Table 15-14. EASR Field Descriptions

15.16 Implementation-Specific Registers (ISR0-7)

The implementation-specific registers are 32-bit special-purpose supervisor-level register accessible with the l.mfspr instruction in supervisor mode.

They are SPR space which can be used by implementations for any purpose. Their presence is indicated by the ISRP bit in the CPU Configuration Register (CPUCFGR).

16 Application Binary Interface

The ABI is currently defined only for 32-bit OpenRISC. When a toolchain is developed for 64-bit, this section will need updating.

16.1 Data Representation

16.1.1 Fundamental Types

Scalar types in the ISO/ANSI C language are based on memory operands definitions from the chapter entitled “Addressing Modes and Operand Conventions” on page 21. Similar relations between architecture and language types can be used for any other language.

Type	C TYPE	SIZEOF	ALIGNMENT (BYTES)	OPENRISC EQUIVALENT
Integral	char	1	1	Signed byte
	signed char			
	unsigned char	1	1	Unsigned byte
	short	2	2	Signed halfword
	signed short			
	unsigned short	2	2	Unsigned halfword
	int	4	4	Signed singleword
	signed int long signed long enum			
unsigned int	4	4	Unsigned singleword	
long long signed long long	8	4	Signed doubleword	
unsigned long long	8	4	Unsigned doubleword	
Pointer	Any-type * Any-type (*) ()	4	4	Unsigned singleword
Floating-point	float	4	4	Single precision float
	double	8	4	Double precision float

Table 16-1. Scalar Types

Prior versions of this table specified a native 8-byte alignment for 8-byte values. Since current OR1200 implementation never required this, and the compiler did not implement it, the specification has changed to match the 32-bit OpenRISC platform in use.

A null pointer of any type must be zero. All floating-point types are IEEE-754 compliant.

The OpenRISC programming model introduces a set of fundamental vector data types, as described by Table 16-2. For vector assignments both sides of an assignment must be of the same vector type.

VECTOR TYPE	SIZEOF	ALIGNMENT (BYTES)	OPENRISC EQUIVALENT
Vector char Vector signed char	8	8	Vector of signed bytes
Vector unsigned char	8	8	Vector of unsigned bytes
Vector short Vector signed short	8	8	Vector of signed halfwords
Vector unsigned short	8	8	Vector of unsigned halfwords
Vector int Vector signed int Vector long Vector signed long	8	8	Vector of signed singlewords
Vector unsigned int	8	8	Vector of unsigned singlewords
Vector float	8	8	Vector of single-precisions

Table 16-2. Vector Types

For alignment restrictions of all types see the section entitled “Aligned and Misaligned Accesses” on page 21.

16.1.2 Aggregates and Unions

Aggregates (structures and arrays) and unions assume the alignment of their most strictly aligned element.

- ✓ An array uses the alignment of its elements.
- ✓ Structures and unions can require padding to meet alignment restrictions. Each element is assigned to the lowest aligned address.

```

struct {
    char C;
};

```

Figure 16-1. Byte aligned, sizeof is 1

```

struct {
    char C;
    char D;
    short S;
    long N;
};

```

Figure 16-2. No padding, sizeof is 8

```

struct {
    char C;
    double D;
    short S;
}

```

Figure 16-3. Padding, sizeof is 16

16.1.3 Bit-fields

C structure and union definitions can have elements defined by a specified number of bits. Table 16-3 describes valid bit-field types and their ranges.

Bit-field Type	Width w [bits]	Range
signed char char unsigned char	1 to 8	-2^{w-1} to $2^{w-1}-1$ 0 to 2^w-1 0 to 2^w-1
signed short short unsigned short	1 to 16	-2^{w-1} to $2^{w-1}-1$ 0 to 2^w-1 0 to 2^w-1
signed int int enum unsigned int signed long long unsigned long	1 to 32	-2^{w-1} to $2^{w-1}-1$ 0 to 2^w-1 0 to 2^w-1 0 to 2^w-1 -2^{w-1} to $2^{w-1}-1$ 0 to 2^w-1 0 to 2^w-1

Table 16-3. Bit-Field Types and Ranges

Bit-fields follow the same alignment rules as aggregates and unions, with the following additions:

- ✓ Bit-fields are allocated from most to least significant (from left to right)
- ✓ A bit-field must entirely reside in a storage unit appropriate for its declared type.
- ✓ Bit-fields may share a storage unit with other struct/union elements, including elements that are not bit-fields. Struct elements occupy different parts of the storage unit.
- ✓ Unnamed bit-fields' types do not affect the alignment of a structure or union

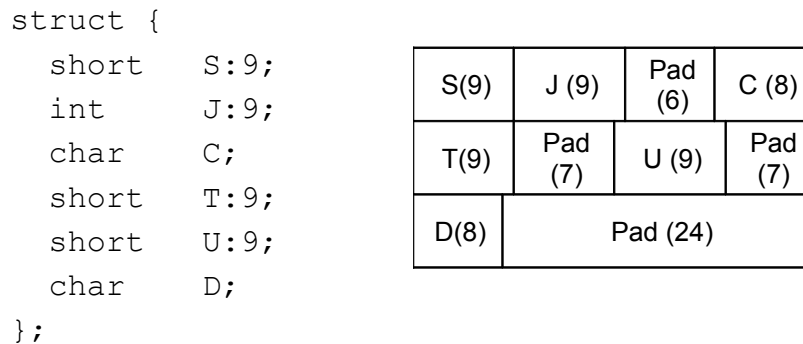

Figure 16-4. Storage unit sharing and alignment padding, sizeof is 12

16.2 Function Calling Sequence

This section describes the standard function calling sequence, including stack frame layout, register usage, parameter passing, and so on. The standard calling sequence requirements apply only to global functions, however it is recommended that all functions use the standard calling sequence.

16.2.1 Register Usage

The OpenRISC 1000 architecture defines 32 general-purpose registers. These registers are 32 bits wide in 32-bit implementations and 64 bits wide in 64-bit implementations.

Register	Preserved across function calls	Usage
R31	No	Temporary register
R30	Yes	Callee-saved register
R29	No	Temporary register
R28	Yes	Callee-saved register
R27	No	Temporary register
R26	Yes	Callee-saved register

Register	Preserved across function calls	Usage
R25	No	Temporary register
R24	Yes	Callee-saved register
R23	No	Temporary register
R22	Yes	Callee-saved register
R21	No	Temporary register
R20	Yes	Callee-saved register
R19	No	Temporary register
R18	Yes	Callee-saved register
R17	No	Temporary register
R16	Yes	Callee-saved register
R15	No	Temporary register
R14	Yes	Callee-saved register
R13	No	Temporary register
R12	No	Temporary register for 64-bit RVH - Return value upper 32 bits of 64-bit value on 32-bit system
R11	No	RV – Return value
R10	Yes	Callee-saved register
R9	Yes	LR – Link address register
R8	No	Function parameter word 5
R7	No	Function parameter word 4
R6	No	Function parameter word 3
R5	No	Function parameter word 2
R4	No	Function parameter word 1
R3	No	Function parameter word 0
R2	Yes	FP - Frame pointer (optional)
R1	Yes	SP - Stack pointer
R0	-	Fixed to zero

Table 16-4. General-Purpose Registers

Some registers have assigned roles:

- R0 [Zero] Holds a zero value.
- R1 [SP] The **stack pointer** holds the limit of the current stack frame. The first 128 bytes below the stack pointer are reserved for leaf functions, and below that are undefined. Stack pointer must be word aligned at all times.
- R2 [FP] The **frame pointer** holds the address of the previous stack frame. Incoming function parameters reside in the previous stack frame and can be accessed at positive offsets from FP. The compiler may use this register for other purposes if instructed.
- R3 through R8 **General-purpose parameters** use up to 6 general-purpose registers. Parameters beyond the sixth word appear on the stack.

- R9 [LR] **Link address** is the location of the function call instruction and is used to calculate where program execution should return after function completion.
- R11 [RV] **Return value** of the function. For *void* functions a value is not defined. For functions returning a union or structure, a pointer to the result is placed into return value register.
- R12 [RVH] **Return value high** of the function. For functions returning 32-bit values this register can be considered temporary register. Note that this holds the less significant bits on big-endian implementations; 32-bit values still go in RV.

On big-endian implementations, R11 is used for the high 32 bits of 64-bit return values and R12 is used for the low 32 bits. On little-endian implementations this is reversed. This matches register order with memory storage.

Furthermore, an OpenRISC 1000 implementation might have several sets of shadowed general-purpose registers. These shadowed registers are used for fast context switching and sets can be switched only by the operating system.

16.2.2 The Stack Frame

In addition to registers, each function has a frame on the run-time stack. This stack grows downward from high addresses. Table 16-5 shows the stack frame organization.

Position	Contents	Frame
FP + 4N	Parameter N	Previous
...	...	
FP + 0	First stack parameter	
FP - 4	Return address	Current
FP - 8	Previous FP value	
FP - 12	Function variables	
...	...	
SP + 0	Subfunction call parameters	Future
SP - 4	For use by leaf functions w/o function prologue/epilogue	
SP - 128		
SP - 132	For use by exception handlers	
SP - 2536		

Table 16-5. Stack Frame

When no compiler optimization is in place, the stack pointer always points to the end of the latest allocated stack frame. However when optimization is in effect the stack pointer may not be updated, so that up to 128 bytes beyond the current stack pointer are in use.

Optimized code will in general not use the frame pointer, freeing it up for use as another temporary register.

All frames must be word aligned.

The first 128 bytes below the current stack frame are reserved for use by optimized code. Exception handlers must guarantee that they will not use this area.

16.2.3 Parameter Passing

Functions receive up to their first 6 arguments in general-purpose parameter registers. No register holds more than one argument, and 64-bit arguments use two adjacent words. If there are more than six words, the remaining arguments are passed on the stack. Structure and union arguments are passed as pointers.

All 64-bit arguments in a 32-bit system are passed using a pair of words when available, in the same way as for other arguments. 64-bit arguments are not aligned. For example *long long arg1*, *long arg2*, *long long arg3* are passed in the following way: *arg1* in *r3&r4*, *arg2* in *r5*, *arg3* in *r6&r7*.

On big-endian implementations the high 32 bits are passed in the lower numbered register of the pair. On little-endian implementations this is reversed.

Individual arguments are not split across registers and stack, and variadic arguments are always put on the stack. For example, `printf(char *fmt, ...)` only takes one register argument, `fmt`.

For C++, the first argument word is the `this` pointer.

16.2.4 Functions Returning Scalars or No Value

A function that returns an integral, pointer or vector/floating-point value places its result in the general-purpose RV register. *void* functions put no particular value in GPR[RV] register.

64-bit return values also use the RVH register, which is otherwise undefined and not preserved across function calls.

16.2.5 Functions Returning Structures or Unions

A function that returns a structure or union places the address of the structure or union in the general-purpose RV register.

A function that returns a structure by value expects the location where that structure is to be placed to be supplied in function parameter word 0 (R3).

16.3 Operating System Interface

16.3.1 Exception Interface

The OpenRISC 1000 exception mechanism allows the processor to change to supervisor mode as a result of external signals, errors or execution of certain instructions. When an exception occurs the following events happen:

- ✓ The address of the interrupted instruction, supervisor register and EA (when relevant) are saved into EPCR, ESR and EEAR registers
- ✓ The machine mode is changed to supervisor mode as per section 6.3, Exception Processing. This includes disabling MMUs and exceptions.

- ✓ The execution resumes from a predefined exception vector address which is different for every exception

Exception Type	Vector Offset[11:0]	SIGNAL	Example
Reset	0x100	None	Reset
Bus Error	0x200	SIGBUS	Unexisting physical location, bus parity error.
Data Page Fault	0x300	SIGSEGV	Unmapped data location or protection violation.
Instruction Page Fault	0x400	SIGSEGV	Unmapped instruction location or protection violation
Tick Timer Interrupt	0x500	None	Process scheduling
Alignment	0x600	SIGBUS	Unaligned data
Illegal Instruction	0x700	SIGILL	Illegal/unimplemented instruction
External Interrupt	0x800	None	Device has asserted an interrupt
D-TLB Miss	0x900	None	DTLB software reload needed
I-TLB Miss	0xA00	None	ITLB software reload needed
Range	0xB00	SIGSEGV	Arithmetic overflow
System Call	0xC00	None	Instruction l.sys
Trap	0xE00	SIGTRAP	Instruction l.trap or debug unit exception.

Table 16-6. Hardware Exceptions and Signals

The significant bits (31-12) of the vector offset address for each exception depend on the setting of the Supervision Register (SR)'s EPH bit and presence and setting of of the Exception Vector Base Address Register (EVBAR), which can specify an offset. For example, in the absence of the EVBAR and with SR[EPH] clear, the offset is zero.

The operating system handles an exception either by completing the faulting exception in a manner transparent to the application, if possible, or by delivering a signal to the application. Table 16-6 shows how hardware exceptions can be mapped to signals if the operating system cannot complete the faulting exception.

16.3.2 Virtual Address Space

For user programs to execute in virtual address space, the memory management unit (MMU) must be enabled. The MMU translates virtual address generated by the running process into physical address. This allows the process to run anywhere in the physical memory and additionally page to a secondary storage.

Processes typically begin with three logical segments, commonly referred as “text”, “data” and “stack”. Additional segments may exist or can be created by the operating system.

16.3.3 Page Size

Memory is organized into pages, which are the system's smallest units of memory allocation. The basic page size is 8KB with some implementations supporting 16MB and 32GB pages.

16.3.4 Virtual Address Assignments

Processes have full access to the entire virtual address space. However the size of a process can be limited by several factors such as a process size limit parameter, available physical memory and secondary storage.

0xFFFF_FFFF	Reserved system area
Start of Stack Growing Down	Stack
Growing Up	Heap
Start of Data Segments	.bss
Start of Program Code	.data
	.text
Start of Dynamic Segment Area	Shared Objects
0x0000_2000	
0x0000_0000	Unmapped

Table 16-7. Virtual Address Configuration

Page at location 0x0 is usually reserved to catch dereferences of NULL pointers.

Usually the beginning address of “.text”, “.data” and “.bss” segments are defined when linking the executable file. The heap is adjusted with facilities such as *malloc* and *free*. The dynamic segment area is adjusted with *mmap*, and the stack size is limited with *setrlimit*.

16.3.5 Stack

Every process has its own stack that is not tied to a fixed area in its address space. Since the stack can change differently for each call of a process, a process should use the stack pointer in general-purpose register r1 to access stack data.

16.3.6 Processor Execution Modes

The OpenRISC 1000 provides two execution modes: user and supervisor. Processes run in user mode and the operating system's kernel runs in supervisor mode. A Process must execute the *l.sys* instruction to switch to supervisor mode, hence requesting service from the operating system. It is suggested that system calls use the same argument passing model as used with function calls, except additional register r11 specifies system call id.

16.4 Position-Independent Code

This section needs to be written. Position-independent code is desired for proper dynamic linking support, which remains to be implemented.

16.5 ELF

The OpenRISC tools use the ELF object file formats and DWARF debugging information formats, as described in *System V Application Binary Interface*, from the Santa Cruz Operation, Inc. ELF and DWARF provide a suitable basis for representing the information needed for embedded applications. Other object file formats are available, such as COFF. This section describes particular fields in the ELF and DWARF formats that differ from the base standards for those formats.

16.5.1 Header Convention

The *e_machine* member of the ELF header contains the decimal value 33906 (hexadecimal 0x8472) that is defined as the name EM_OR32.

The *e_ident* member of the ELF header contains values as shown in Table 16-8.

OR32 ELF e_ident Fields		
e_ident[EI_CLASS]	ELFCLASS32	For all 32-bit implementations
e_ident[EI_DATA]	ELFDATA2MSB	For all implementations

Table 16-8. e_ident Field Values

The *e_flags* member of the ELF header contains values as shown in Table 16-9.

OR32 ELF e_flags		
HAS_RELOC	0x01	Contains relocation entries
EXEC_P	0x02	Is directly executable
HAS_LINENO	0x04	Has line number information
HAS_DEBUG	0x08	Has debugging information
HAS_SYMS	0x10	Has symbols
HAS_LOCALS	0x20	Has local symbols
DYNAMIC	0x40	Is dynamic object
WP_TEXT	0x80	Text section is write protected
D_PAGED	0x100	Is dynamically paged

Table 16-9. e_flags Field Values

16.5.2 Sections

There are no OpenRISC section requirements beyond the base ELF standards.

16.5.3 Relocation

This section describes values and algorithms used for relocations. In particular, it describes values the compiler/assembler must leave in place and how the linker modifies those values.

Name	Value	Size	Calculation
R_OR32_NONE	0	0	None
R_OR32_32	1	32	A
R_OR32_16	2	16	A & 0xffff
R_OR32_8	3	8	A & 0xff
R_OR32_CONST	4	16	A & 0xffff
R_OR32_CONSTH	5	16	(A >> 16) & 0xffff
R_OR32_JUMPTARG	6	28	(S + A - P) >> 2

Key *S* indicates the final value assigned to the symbol referenced in the relocation record. Key *A* is the added value specified in the relocation record. Key *P* indicates the address of the relocation (e.g., the address being modified).

17 Machine code reference

This section contains a table of all instructions including their instruction format.

Instruction	Mnemonic	Function	Page
000000NNNNNNNNNNNNNNNNNNNNNNNNNNNNNN	l.j	Jump	
000001NNNNNNNNNNNNNNNNNNNNNNNNNNNNNN	l.jal	Jump and Link
