## Introduction

CORDIC (Coordinate Rotation Digital Computer) is a method for computing elementary functions using minimal hardware such as shifts, adds/subs and compares.

CORDIC works by rotating the coordinate system through constant angles until the angle is reduces to zero. The angle offsets are selected such that the operations on X and Y are only shifts and adds.

### 1.1 The numbers

This section describes the mathematics behind the CORDIC algorithm. Those not interested in the numbers can skip this section.

The CORDIC algorithm performs a planar rotation. Graphically, planar rotation means transforming a vector ( $\mathrm{Xi}, \mathrm{Yi}$ ) into a new vector $(\mathrm{Xj}, \mathrm{Yj})$.

Using a matrix form, a planar rotation for a vector of $(\mathrm{Xi}, \mathrm{Yi})$ is defined as

$$
\left[\begin{array}{c}
X_{j}  \tag{1}\\
Y_{j}
\end{array}\right]=\left[\begin{array}{cc}
\cos \theta & -\sin \theta \\
\sin \theta & \cos \theta
\end{array}\right]\left[\begin{array}{c}
X_{i} \\
Y_{i}
\end{array}\right]
$$

The $\theta$ angle rotation can be executed in several steps, using an iterative process. Each step completes a small part of the rotation. Many steps will compose one planar rotation. A single step is defined by the following equation:

$$
\left[\begin{array}{c}
X_{n+1}  \tag{2}\\
Y_{n+1}
\end{array}\right]=\left[\begin{array}{cc}
\cos \theta_{n} & -\sin \theta_{n} \\
\sin \theta_{n} & \cos \theta_{n}
\end{array}\right]\left[\begin{array}{c}
X_{n} \\
Y_{n}
\end{array}\right]
$$

Equation 2 can be modified by eliminating the $\cos \theta_{n}$ factor.

$$
\left[\begin{array}{c}
X_{n+1}  \tag{3}\\
Y_{n+1}
\end{array}\right]=\cos \theta_{n}\left[\begin{array}{cc}
1 & -\tan \theta_{n} \\
\tan \theta_{n} & 1
\end{array}\right]\left[\begin{array}{c}
X_{n} \\
Y_{n}
\end{array}\right]
$$

Equation 3 requires three multiplies, compared to the four needed in equation 2.
Additional multipliers can be eliminated by selecting the angle steps such that the tangent of a step is a power of 2 . Multiplying or dividing by a power of 2 can be implemented using a simple shift operation.

The angle for each step is given by
$\theta_{n}=\arctan \left(\frac{1}{2^{n}}\right)$
All iteration-angles summed must equal the rotation angle $\theta$.

$$
\begin{equation*}
\sum_{n=0}^{\infty} S_{n} \theta_{n}=\theta \tag{5}
\end{equation*}
$$

where

$$
\begin{equation*}
S_{n}=\{-1 ;+1\} \tag{6}
\end{equation*}
$$

This results in the following equation for $\tan \theta_{n}$

$$
\begin{equation*}
\tan \theta_{n}=S_{n} 2^{-n} \tag{7}
\end{equation*}
$$

Combining equation 3 and 7 results in

$$
\left[\begin{array}{c}
X_{n+1}  \tag{8}\\
Y_{n+1}
\end{array}\right]=\cos \theta_{n}\left[\begin{array}{cc}
1 & -S_{n} 2^{-n} \\
S_{n} 2^{-n} & 1
\end{array}\right]\left[\begin{array}{c}
X_{n} \\
Y_{n}
\end{array}\right]
$$

Besides for the $\cos \theta_{n}$ coefficient, the algorithm has been reduced to a few simple shifts and additions. The coefficient can be eliminated by pre-computing the final result. The first step is to rewrite the coefficient.

$$
\begin{equation*}
\cos \theta_{n}=\cos \left(\arctan \left(\frac{1}{2^{n}}\right)\right) \tag{9}
\end{equation*}
$$

The second step is to compute equation 9 for all values of ' $n$ ' and multiplying the results, which we will refer to as K.
$K=\frac{1}{P}=\prod_{n=0}^{\infty} \cos \left(\arctan \left(\frac{1}{2^{n}}\right)\right) \approx 0.607253$
K is constant for all initial vectors and for all values of the rotation angle, it is normally referred to as the congregate constant. The derivative P (approx. 1.64676) is defined here because it is also commonly used.

We can now formulate the exact calculation the CORDIC performs.
$\left\{\begin{array}{c}X_{j}=K\left(X_{i} \cos \theta-Y_{i} \sin \theta\right) \\ Y_{j}=K\left(Y_{i} \cos \theta+X_{i} \sin \theta\right)\end{array}\right.$

Because the coefficient K is pre-computed and taken into account at a later stage, equation 8 may be written as
$\left[\begin{array}{c}X_{n+1} \\ Y_{n+1}\end{array}\right]=\left[\begin{array}{cc}1 & -S_{n} 2^{-n} \\ S_{n} 2^{-n} & 1\end{array}\right]\left[\begin{array}{l}X_{n} \\ Y_{n}\end{array}\right]$
or as

$$
\left\{\begin{array}{l}
X_{n+1}=X_{n}-S_{n} 2^{-2 n} Y_{n}  \tag{13}\\
Y_{n+1}=Y_{n}+S_{n} 2^{-2 n} X_{n}
\end{array}\right.
$$

At this point a new variable called ' $Z$ ' is introduced. $Z$ represents the part of the angle $\theta$ which has not been rotated yet.

$$
\begin{equation*}
Z_{n+1}=\theta-\sum_{i=0}^{n} \theta_{i} \tag{14}
\end{equation*}
$$

For every step of the rotation Sn is computed as a sign of Zn .

$$
S_{n}= \begin{cases}-1 & \text { if } Z_{n}<0  \tag{15}\\ +1 & \text { if } Z_{n} \geq 0\end{cases}
$$

Combining equations 5 and 15 results in a system which reduces the not rotated part of angle $\theta$ to zero.
Or in a program-like style:
For $\mathrm{n}=0$ to [inf]
If $(\mathrm{Z}(\mathrm{n})>=0)$ then

$$
\mathrm{Z}(\mathrm{n}+1):=\mathrm{Z}(\mathrm{n})-\operatorname{atan}\left(1 / 2^{\wedge} \mathrm{n}\right) ;
$$

Else

$$
\mathrm{Z}(\mathrm{n}+1):=\mathrm{Z}(\mathrm{n})+\operatorname{atan}\left(1 / 2^{\wedge} \mathrm{n}\right) ;
$$

End if;
End for;

The $\operatorname{atan}\left(1 / 2^{\wedge} \mathrm{i}\right)$ is pre-calculated and stored in a table. [inf] is replaced with the required number of iterations, which is about 1 iteration per bit ( 16 iterations yield a 16bit result).

If we add the computation for X and Y we get the program-like style for the CORDIC core.

For $\mathrm{n}=0$ to [inf]

$$
\text { If }(\mathrm{Z}(\mathrm{n})>=0) \text { then }
$$

$$
\begin{aligned}
\mathrm{X}(\mathrm{n}+1) & :=\mathrm{X}(\mathrm{n})-\left(\mathrm{Yn} / 2^{\wedge} \mathrm{n}\right) ; \\
\mathrm{Y}(\mathrm{n}+1) & :=\mathrm{Y}(\mathrm{n})+\left(\mathrm{Xn} / 2^{\wedge} \mathrm{n}\right) ; \\
\mathrm{Z}(\mathrm{n}+1) & :=\mathrm{Z}(\mathrm{n})-\operatorname{atan}\left(1 / 2^{\wedge} \mathrm{n}\right) ;
\end{aligned}
$$

Else

$$
\begin{aligned}
\mathrm{X}(\mathrm{n}+1) & :=\mathrm{X}(\mathrm{n})+\left(\mathrm{Yn} / 2^{\wedge} \mathrm{n}\right) ; \\
\mathrm{Y}(\mathrm{n}+1) & :=\mathrm{Y}(\mathrm{n})-\left(\mathrm{Xn} / 2^{\wedge} \mathrm{n}\right) ; \\
\mathrm{Z}(\mathrm{n}+1) & :=\mathrm{Z}(\mathrm{n})+\operatorname{atan}\left(1 / 2^{\wedge} \mathrm{n}\right) ;
\end{aligned}
$$

End if;
End for;

This algorithm is commonly referred to as driving Z to zero. The CORDIC core computes:
$\left\lfloor X_{j}, Y_{j}, Z_{j}\right\rfloor=\left[P\left(X_{i} \cos \left(Z_{i}\right)-Y_{i} \sin \left(Z_{i}\right)\right), P\left(Y_{i} \cos \left(Z_{i}\right)+X_{i} \sin \left(Z_{i}\right)\right), 0\right]$

There's a special case for driving Z to zero:

$$
\begin{aligned}
& X_{i}=\frac{1}{P}=K \approx 0.60725 \\
& Y_{i}=0 \\
& Z_{i}=\theta \\
& \left\lfloor X_{j}, Y_{j}, Z_{j}\right\rfloor=[\cos \theta, \sin \theta, 0]
\end{aligned}
$$

Another scheme which is possible is driving Y to zero. The CORDIC core then computes:

$$
\left[X_{j}, Y_{j}, Z_{j}\right]=\left[P \sqrt{X_{i}^{2}+Y_{i}^{2}}, 0, Z_{i}+\arctan \left(\frac{Y_{i}}{X_{i}}\right)\right]
$$

For this scheme there are two special cases:

1) $\quad X_{i}=X$

$$
\begin{aligned}
& Y_{i}=Y \\
& Z_{i}=0
\end{aligned}
$$

$$
\left[X_{j}, Y_{j}, Z_{j}\right]=\left[P \sqrt{X_{i}^{2}+Y_{i}^{2}}, 0, \arctan \left(\frac{Y_{i}}{X_{i}}\right)\right]
$$

2) $\quad X_{i}=1$

$$
\begin{aligned}
& Y_{i}=a \\
& Z_{i}=0 \\
& {\left[X_{j}, Y_{j}, Z_{j}\right]=\left\lfloor P \sqrt{1+a^{2}}, 0, \arctan (a)\right\rfloor}
\end{aligned}
$$

## 2

## Architecture

All CORDIC Processor cores are built around three fundamental blocks. The preprocessor, the post-processor and the actual CORDIC core. The CORDIC core is built using a pipeline of CordicPipe blocks. Each CordicPipe block represents a single step in the iteration processes.

### 2.1 Pre- and Post-Processors

Because of the arctan table used in the CORDIC algorithm, it only converges in the range of $-1(\mathrm{rad})$ to $+1(\mathrm{rad})$. To use the CORDIC algorithm over the entire $2 \pi$ range the inputs need to be manipulated to fit in the -1 to +1 rad. range. This is handled by the preprocessor. The post-processor corrects this and places the CORDIC core's results in the correct quadrant. It also contains logic to correct the P-factor.

### 2.2 CORDIC

The CORDIC core is the heart of the CORDIC Processor Core. It performs the actual CORDIC algorithm. All iterations are performed in parallel, using a pipelined structure. Because of the pipelined structure the core can perform a CORDIC transformation each clock cycle. Thus ensuring the highest throughput possible.

### 2.3 CORDIC Pipeline

Each pipe or iteration step is performed by the CordicPipe core. It contains the atan table for each iteration and the logic needed to manipulate the $\mathrm{X}, \mathrm{Y}$ and Z values.

## 3

# Polar to Rectangular Conversion 

Only CORDIC and CordicPipe are coded so far.

## Coming soon.

## 4

## Sine and Cosine calculations

Sine and Cosine can be calculated using the first CORDIC scheme which calculates:

$$
\left\lfloor X_{j}, Y_{j}, Z_{j}\right\rfloor=\left[P\left(X_{i} \cos \left(Z_{i}\right)-Y_{i} \sin \left(Z_{i}\right)\right), P\left(Y_{i} \cos \left(Z_{i}\right)+X_{i} \sin \left(Z_{i}\right)\right), 0\right]
$$

By using the following values as inputs

$$
\begin{aligned}
& X_{i}=\frac{1}{P}=\frac{1}{1.6467} \approx 0.60725 \\
& Y_{i}=0 \\
& Z_{i}=\theta
\end{aligned}
$$

the core calculates:

$$
\left\lfloor X_{j}, Y_{j}, Z_{j}\right\rfloor=[\cos \theta, \sin \theta, 0]
$$

The input Z takes values from -180degrees to +180 degrees where:
$0 x 8000=-180$ degrees
$0 x E F F F=+80$ degrees
But the core only converges in the range -90 degrees to +90 degrees.

The other inputs and the outputs are all in the range of -1 to +1 . The congregate constant $P$ represented in this format results in:

$$
X i=2^{15} \bullet P=19898(d e c)=4 D B A(h e x)
$$

## Example:

Calculate sine and cosine of 30degrees.
First the angle has to be calculated:

$$
\begin{aligned}
& 360 \mathrm{deg} \equiv 2^{16} \\
& 1 \operatorname{deg} \equiv \frac{2^{16}}{360} \\
& 30 \operatorname{deg} \equiv \frac{2^{16}}{360} \bullet 30 \approx 5461(\text { dec })=1555(\text { hex })
\end{aligned}
$$

The core calculates the following sine and cosine values for $\mathrm{Zi}=5461$ :
Sin : 16380 (dec) $=3$ FFC(hex)
Cos: 28381 (dec) $=6 \mathrm{EDD}$ (hex)
The outputs represent values in the -1 to +1 range. The results can be derived as follows:

$$
\begin{array}{ll}
2^{15} \equiv 1.0 & 2^{15} \equiv 1.0 \\
16380 \equiv \frac{1.0}{2^{15}} \bullet 16380=0.4999 & 28381 \equiv \frac{1.0}{2^{15}} \bullet 28381=0.8661
\end{array}
$$

Whereas the result should have been 0.5 and 0.8660 .

|  | 0 deg | 30 deg | 45 deg | 60 deg | 90 deg |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Sin | 0x01CC | 0x3FFC | 0x5A82 | 0x6EDC | $0 \times 8000$ |
| Cos | $0 \times 8000$ | $0 \times 6 \mathrm{EDD}$ | 0x5A83 | $0 \times 4000$ | $0 \times 01 \mathrm{CC}$ |
| Sin | 0.01403 | 0.49998 | 0.70709 | 0.86609 | 1.00000 |
| $\operatorname{Cos}$ | 1.00000 | 0.86612 | 0.70712 | 0.50000 | 0.01403 |

Table 1: $\mathrm{Sin} /$ Cos outputs for some common angles
Although the core is very accurate small errors can be introduced by the algorithm (see example and results table). This should be only a problem when using the core over the entire output range, because the difference between $+1(0 x 7 F F F)$ and $-1(0 x 8000)$ is only 1 bit.

### 4.1 Core structure

### 4.2 IO Ports

| Port | Width | Direction | Description |
| :--- | :--- | :--- | :--- |
| CLK | 1 | Input | System Clock |
| ENA | 1 | Input | Clock enable signal |
| Ain | 16 | Input | Angel input |
| Sin | 16 | Output | Sine output |
| Cos | 16 | Output | Cosine output |

Table 2: List of IO Ports for Sine/Cosine CORDIC Core

### 5.3 Synthesis Results

| Vendor | Family | Device | Resource usage | Max. Clock speed |
| :--- | :--- | :--- | :--- | :--- |
| Xilinx | Spartan-II | XC2S100-6 | 387slices | 116 MHz |

Table 3: Synthesis results for Rectangular to Polar CORDIC Core

## 5

## Rectangular to Polar Conversion

The rectangular to polar coordinate processor is built around the second CORDIC scheme which calculates:

$$
\left[X_{j}, Y_{j}, Z_{j}\right]=\left\lfloor P \sqrt{1+a^{2}}, 0, \arctan (a)\right\rfloor
$$

It takes two 16bit signed words as inputs (Xin, Yin), which are the rectangular coordinates of a point in a 2-dimensional space. The core returns the equivalent Polar coordinates where Rout is the radius and Aout the angle or $\theta$.

### 5.1 Core structure

### 5.2 IO Ports

| Port | Width | Direction | Description |
| :--- | :--- | :--- | :--- |
| CLK | 1 | Input | System Clock |
| ENA | 1 | Input | Clock enable signal |
| Xin | 16 | Input | X-coordinate input. Signed value |
| Yin | 16 | Input | Y-coordinate input. Signed value |
| Rout | 20 | Output | Radius output. Unsigned value. |
| Aout | 20 | Output | Angle $(\theta)$ output. Singed/Unsigned value. |

Table 4: List of IO Ports for Rectangular to Polar CORDIC Core

The outputs are in a fractional format. The upper 16bits represent the decimal value and the lower 4bits represent the fractional value.
The angle output can be used signed and unsigned, because it represents a circle; a - 180 degree angle equals a +180 degrees angle, and a -45 degrees angle equals $a+315$ degrees angle.

### 5.3 Synthesis Results

The table below shows some synthesis results using a pipeline of 15 stages.

| Vendor | Family | Device | Resource usage | Max. Clock speed |
| :--- | :--- | :--- | :--- | :--- |
| Altera | ACEX | EP1K50-1 | 2190lcells | 68 MHz |
| Xilinx | Spartan-II | XC2S100-6 | 704slices | 93 MHz |

Table 5: Synthesis results for Rectangular to Polar CORDIC Core
