# 1. Introduction

openVeriFLA is an FPGA logic analyzer. The host computer software is written in Java, so it is platform independent. The HDL code is written in Verilog and VHDL, in both languages being fully supported. This project helps in on-board testing and debugging of the FPGA projects. This is done by real-time capturing and then graphically displaying the signals transitions that happen inside the FPGA chip. Having a didactic scope, openVeriFLA is designed & tested on and for small projects.

openVeriFLA is distributed under the GNU GPL license (the UART sources have a more generous license – written in the source code). It can be downloaded from <https://opencores.org/project/openverifla>. The user manual is released under CC-BY-SA license.

Keep the sources near you, as these will be referenced in this manual.

## 2. Concept

The main architecture of the openVeriFLA logic analyzer is shown in the figure below. The logic analyzer has two sides, the FPGA part and the host computer one. These communicates via the host computer interface cable to the FPGA board.

Fig. Main architecture of the logic analyzer

The openVeriFLA FPGA modules are implemented in Verilog HDL. In order to use the logic analyzer, these modules must be implemented in the FPGA chip along with the user application. The openVeriFLA modules capture the signal transitions of the monitored lines and send the data capture to the host computer for graphical visualization and future analyze.

The host computer part of the application is implemented in the Java language. The java application receives the captured data and saves it on the disk in a file named *capture.v*. This file is a behavioural verilog HDL file. An Verilog HDL simulator with a graphical viewer for the signals is necessary in order to simulate *capture.v* and view the captured data.

A memory word contains a captured data line and the time that this data line is constant. There are also reserved words which may specify:  
- an empty and not used memory cell (LA\_MEM\_EMPTY\_SLOT)  
- the pointer to the tail of the before trigger queue which is stored in the last memory word.

The memory size and memory word length are parameterizable. The control-panel of the logic analyzer is the *common\_internal\_verifla.v* file. The other parameters of this file will be explained later.

### 3. Prerequisites

In order to test openVeriFLA, one will need as hardware a FPGA board and a PL2303TA USB to TTL serial converter.

Fig. PL2303TA USB to TTL serial converter (image from ebay.com)

Only three pins from the FPGA board, named GND, TX and RX will be connected to (in order) black, white and green (because is cross-over connection). So, the TX from the FPGA board is connected to the RX cable wire and vice versa. This way, the FPGA board is connected to a host computer. The red cable wire (+5V) remains unconnected.

At the software level, Windows or Linux with Java JDK (or at least Java JRE) and the FPGA development program (like Xilinx ISE) is needed.

## 4. Case study: simple counters capture

### 4.1. Using openVeriFLA in a HDL module

Instantiating the openVeriFLA top module in a HDL module is shown in the figure below. Please note that cntb and cnta can have arbitrary width.

```
module counters(cntb,
               clk, reset,
               //top_of_verifla transceiver
               uart_XMIT_dataH, uart_REC_dataH);

input clk, reset;
output [7:0] cntb;
//top_of_verifla transceiver
input uart_REC_dataH;
output uart_XMIT_dataH;

// Simple counters
reg [7:0] cntb, cnta;
always @(posedge clk or posedge reset)
begin
    if(reset) begin
        cntb = 0;
        cnta = 0;
    end else begin
        if((cnta & 1) && (cntb < 16'hf0))
            cntb = cntb+1;
        cnta = cnta+1;
    end
end

// VeriFLA
top_of_verifla verifla (.clk(clk), .rst_l(!reset), .sys_run(1'b1),
                       .data_in({cntb, cnta}),
                       // Transceiver
                       .uart_XMIT_dataH(uart_XMIT_dataH), .uart_REC_dataH(
uart_REC_dataH));

endmodule
```

Fig. Instantiating openVeriFLA in the counters module

One must instantiate *top\_of\_verifla* module and pass the following signals to openVeriFLA:

- *clk*, which is the board clock
- *rst\_l*, which is the *top\_of\_verifla* reset signal and is active low
- *sys\_run*, which instructs openVeriFLA whether to immediately start a data capture or wait for the user *run* command
- *data\_in* which contains the signals from the counters module that will be captured
- *uart\_XMIT\_dataH* which is the openVeriFLA serial transmission line (TX)
- *uart\_REC\_dataH* which is the openVeriFLA serial reception line (RX)

The signal transitions are captured on-the-fly by the openVeriFLA modules and then will be sent to the host computer, where will be prepared to be graphically displayed.

The FPGA board clk frequency (in Hz) must be written in the *inc\_of\_verifla.v* file before synthesis; this is required by the UART modules.

Note that openVeriFLA samples data @(posedge clk).

Part of the openVeriFLA synthesis report of the Xilinx ISE tools is shown in the table below (for the counters example).

Xilinx Spartan 3E 1600	
Minimum clock period:	9.089 ns
Number of Slices:	2% (394)
Number of Slice Flip Flops:	1% (242)
Number of 4 input LUTs:	2% (677)
Number of bonded IOBs:	4% (12)
Number of GCLKs:	4% (1 of 24)

Table. The FPGA occupied resources

### 4.3 The host computer Java application

First, the *Verifla.java* source must be compiled by running *compile.sh* on Linux (with bash) or *compile.bat* on Windows; this will generate the *VeriFLA.class*. In order to receive the grabbed data from the FPGA chip, the *VeriFLA.class* is run on the host computer. The communication with the openVeriFLA modules is made via the usb-to-serial interface between the host computer and the FPGA development board; the *VeriFLA* class uses the *jssc.jar* UART library. This way, the signals capture will be sent to the host computer and saved in a form which can be displayed graphically.

On Linux, the *VeriFLA.class* is run with the following command (on Windows, one must replace *sudo ./run.sh* with *run.bat*):

```
$ sudo ./run.sh VeriFLA verifla_properties_counters.txt
or
$ sudo ./run.sh VeriFLA verifla_properties_counters.txt 1
```

Fig. How to run the *VeriFLA.class*

This scripts include in CLASSPATH the path to *jssc.jar*.

In the first case, *VeriFLA* waits for data captured to arrive on the UART serial line, while in the second case, it first sends to the FPGA the command *run* which instructs it to start a new capture and send it on the UART serial line.

After the class is run as shown, the openVeriFLA modules are instructed to start a new capture and after the capture is finished, to send the capture to the host computer.

Now, these modules wait for signal events on the monitored lines.

The java application gets the capture and builds the *capture.v* verilog file. After this, the *capture.v* can be added and simulated in a verilog simulator (e.g. Xilinx ISE or Icarus) project. The result is shown in the figures below.

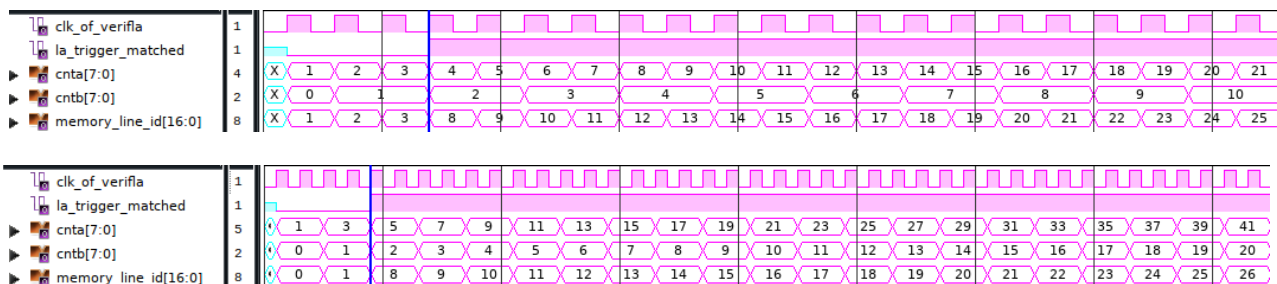

Fig. Simulation of *capture.v*

The *la\_trigger\_matched* shows the moment when the trigger event appeared

and *memory\_line\_id* is the index in the captured data memory (used as debug).

In the first figure, the monitor was configured to capture *cntb* and *cnta* whenever a bit of these signal changes. The trigger moment was set such as *cntb*=2 and *cnta*=4 (*LA\_TRIGGER\_VALUE*=16'h0204, *LA\_TRIGGER\_MASK*=16'hffff, *LA\_TRACE\_MASK*=16'hffff).

In the second figure, the monitor was configured (*LA\_TRIGGER\_VALUE*=16'h0200, *LA\_TRIGGER\_MASK*=16'hff00, *LA\_TRACE\_MASK*=16'hff00) to capture *cntb* and *cnta* only when *cntb* changes. So we can store in the same memory higher values of *cntb* and *cnta* (for example when *memory\_line\_id* is 20, in the first figure *cntb* is 8 and *cnta* is 16 and in the second figure *cntb* is 14 and *cnta* is 29). It must be mentioned the fact that in the second figure the trigger event appears when *cntb*=2 and, for this value, it corresponds two values of *cnta* (4 and 5) - the last value being kept by *openverifla*.

In the *capture.v* simulation, *run* command was necessary, to reach the *\$stop* instruction of the *capture.v*.

## 5. Configuration parameters

### 5.1 The host computer application parameters

The java application takes its parameters from a properties file. This file contains general parameters and application-specific parameters, like the names of the signals to be captured. An example is the *verifla\_properties\_counters.txt* file which is tuned for the counters example. Each parameter name starts with "LA." (here this prefix is trimmed). The important parameters are:

- the UART serial *portName* and *baudRate*;
- *memWords* represents the size of the memory used to store the capture
- data input width and identical samples bits (clones) must be multiples of 8 and are stored in *dataWordLenBits* and *clonesWordLenBits*
- the index in memory where the trigger event appeared is stored in *triggerMatchMemAddr*; it also delimits the before and after trigger queues
- the verilog signals passed to *top\_of\_verifla* module are grouped. Each group of signals is defined by a number of group parameters. First is *groupName* which should be the same as the verilog signal name. The *groupSize* represents the number of the signal lines in the group and is the same with the size of the verilog signal. Sum of the *groupSize* parameter from all groups must be equal to *totalSignals*. The *groupEndian* specifies if the data represented by the group is in big-endian or low-endian format. Each group has an unique id specified after at the end of the each parameter.
- *timescaleUnit*, *timescalePrecision* used for the verilog timescale line in *capture.v* and *clockPeriod* is the period of the development board clock

### 5.2. The FPGA parameters files

The clock frequency of *openVeriFLA* and the UART baudrate must be set in the *inc\_of\_verifla.v* file. This is used by the UART modules to compute the *uart\_clk*. If the clock frequency of *openVeriFLA* is lower than 50 Mhz, then the baudrate must be lower than 115200 (for example 9600).

The control-panel of the logic analyzer is the *common\_internal\_verifla.v* file. It contains the configurable parameters of the logic analyzer.

- *LA\_MEM\_WORDLEN\_BITS* represents the length in bits of a memory word; it is made of *LA\_DATA\_INPUT\_WORDLEN\_BITS* (the length in bits of data input) and *LA\_IDENTICAL\_SAMPLES\_BITS* (the length in bits of the identical samples number) which means the number of clock periods that the data remains constant;

- LA\_MEM\_EMPTY\_SLOT is the value that sets every memory line when cleaning the memory
  - LA\_TRIGGER\_MASK specifies the bits to be considered when checking for the trigger value; it is used to mask the LA\_TRIGGER\_VALUE and the capture data when these two are compared.
  - in LA\_TRACE\_MASK, the signals that are with 0 will be traced only when one or more signals that are with 1 change;
  - LA\_TRIGGER\_MATCH\_MEM\_ADDR is the index in memory where the trigger event appeared;
  - when the memory is full or it were captured
- LA\_MAX\_SAMPLES\_AFTER\_TRIGGER samples, the data capture is sent to the host computer.
- in order to represent an interval of time slots when the monitored lines are constant, the parameter LA\_MAX\_IDENTICAL\_SAMPLES is the maximum identical samples number allowed to be stored in a memory word (it is built on LA\_IDENTICAL\_SAMPLES\_BITS).

## 6. VHDL

The verilog sources were translated line by line in vhdl. Every .v file is .vhd in the vhdl sources. Everything specified in this manual for verilog is valid in the vhdl implementation.

## 7. Change log

### 2.4c

- LA\_MEM\_CLEAN\_BEFORE\_RUN has no use now
- mem-clean-at-reset is no longer necessary

### 2.3

- LA\_TRACE\_MASK

### 2.2.f

- commit 35: hairstyle for vhdl monitor and verilog memory
- commit 34: in java, read all capture as a whole from the serial driver

### 2.2.e

- bug correction for the case when the repeat count of the last sample is 1 (thank you Al Williams).

### 2.2.d

- split mon\_run command in sys\_run and user\_run and clean memory at user\_run.
- vhdl code for monitor changed such that at reset we can start with any state (debug)

### 2.2.c

- clean memory at init (XST compiles it)

### 2.2.a

- vhdl support
- mon\_run\_reg in verifla monitor

### 2.1.g

- instructions regarding the size of BAUDRATE param of UART
- add parameter *baudRate* to openVeriFLA java properties file
- rename of IDLE in IDLE states in UART and 3'd07 in 4'd07 for u\_rec

### 2.1.e

- user readable form for single\_pulse\_of\_verifla.v
- LA\_MEM\_CLEAN\_BEFORE\_RUN is a parameter now (not a `define)

### 2.1d

- all openVeriFLA modules and HDL files end with “\_of\_verifla”

### 2.1

- LA\_INIT\_MEM\_AT\_RESET
- single clock shared by VeriFLA and UART

### 2.0

- new memory layout
- new UART drivers
